

Week 4 – Stereo Reconstruction

Slides from A. Zisserman & S. Lazebnik

Overview

- Single camera geometry
 - Recap of Homogenous coordinates
 - Perspective projection model
 - Camera calibration
- Stereo Reconstruction
 - Epipolar geometry
 - Stereo correspondence
 - Triangulation

Single camera geometry

Projection

a 3d world is represented in 2d space

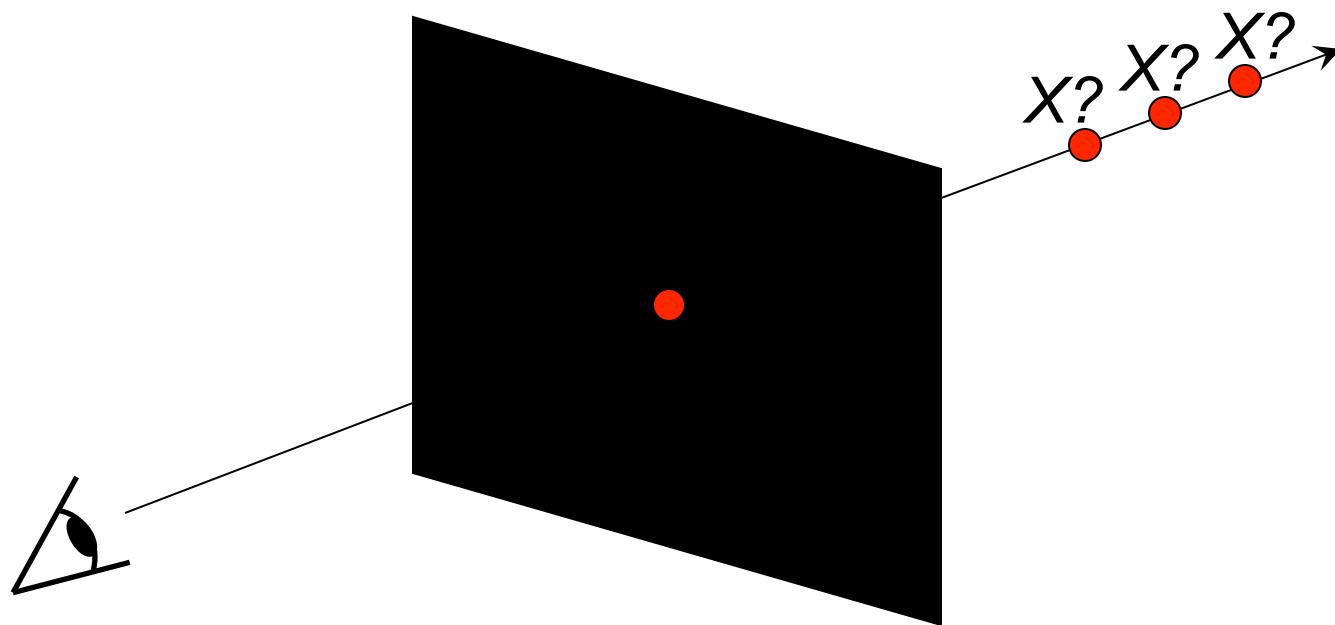

Projection

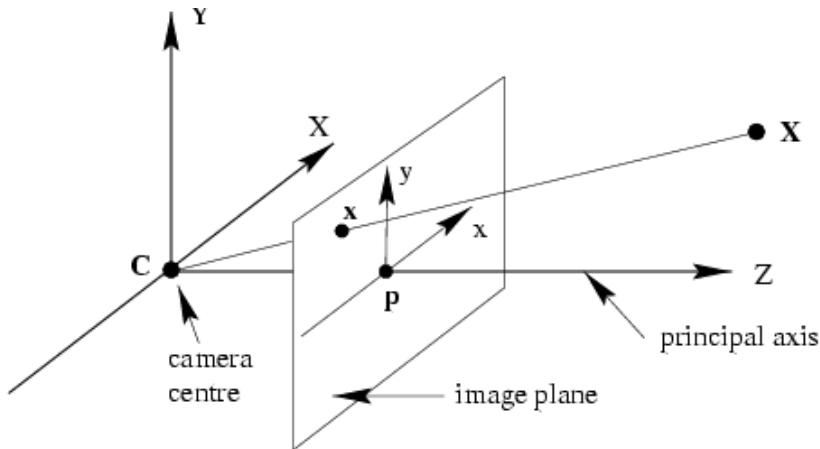

CoolOpticalIllusions.com

Projective Geometry

- Recovery of structure from one image is inherently ambiguous
- Today focus on geometry that maps world to camera image

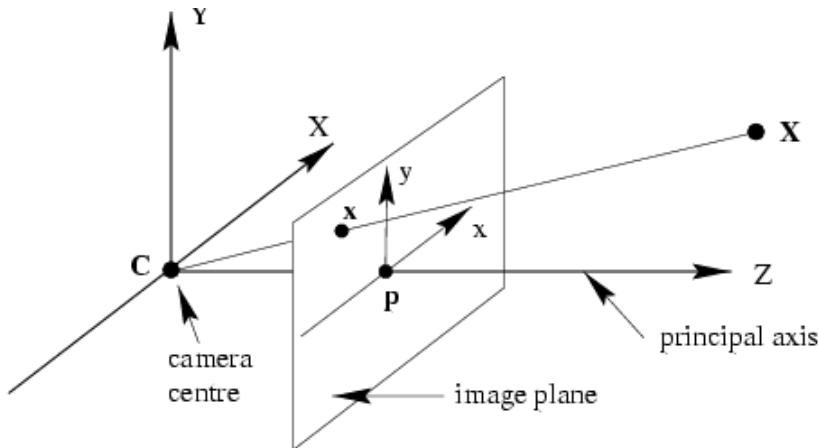

Recall: Pinhole camera model

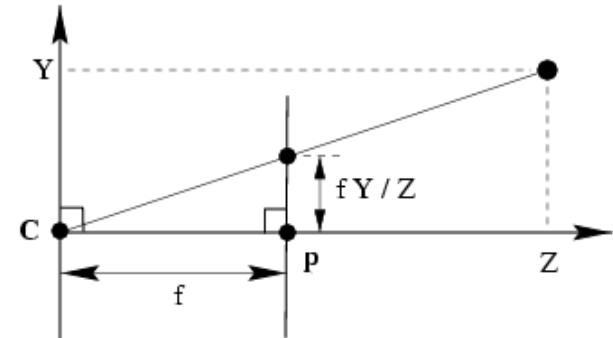

- **Principal axis:** line from the camera center perpendicular to the image plane
- **Normalized (camera) coordinate system:** camera center is at the origin and the principal axis is the z-axis

Recall: Pinhole camera model

mapping on an image plane

$$(X, Y, Z) \mapsto (fX/Z, fY/Z)$$

$$\begin{pmatrix} X \\ Y \\ Z \\ 1 \end{pmatrix} \mapsto \begin{pmatrix} fX \\ fY \\ Z \end{pmatrix} = \begin{bmatrix} f & & & 0 \\ & f & & 0 \\ & & 1 & 0 \end{bmatrix} \begin{pmatrix} X \\ Y \\ Z \\ 1 \end{pmatrix} \quad \mathbf{X} = \mathbf{P}\mathbf{X}$$

Recap: Homogeneous coordinates

- Is this a linear transformation? $(x, y, z) \rightarrow (f \frac{x}{z}, f \frac{y}{z})$
 - no—division by z is nonlinear

Trick: add one more coordinate:

$$(x, y) \Rightarrow \begin{bmatrix} x \\ y \\ 1 \end{bmatrix}$$

homogeneous image
coordinates

$$(x, y, z) \Rightarrow \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix}$$

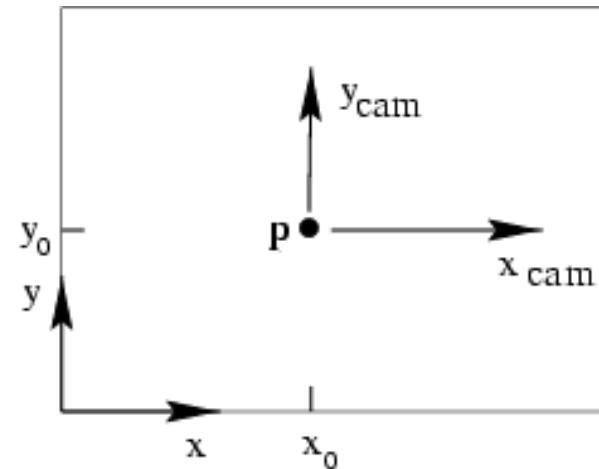

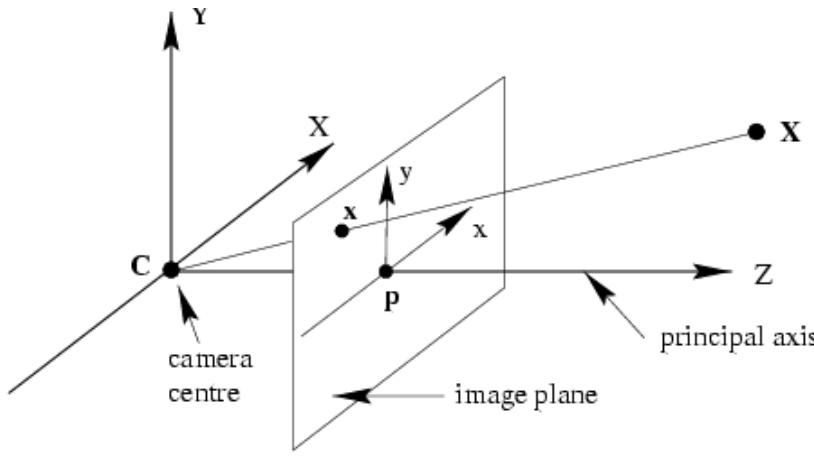

homogeneous scene
coordinates

Converting *from* homogeneous coordinates

$$\begin{bmatrix} x \\ y \\ w \end{bmatrix} \Rightarrow (x/w, y/w)$$

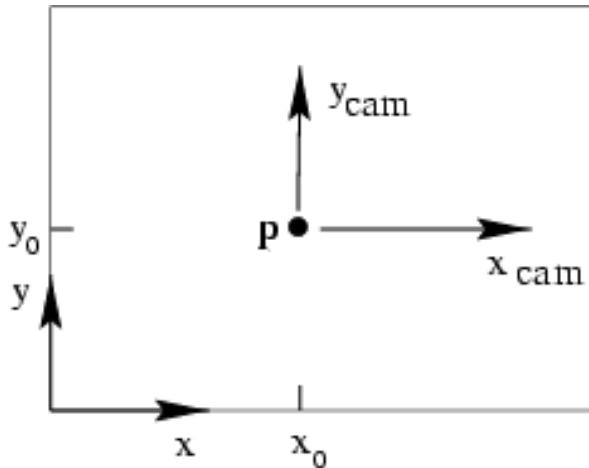

$$\begin{bmatrix} x \\ y \\ z \\ w \end{bmatrix} \Rightarrow (x/w, y/w, z/w)$$

Principal point

- **Principal point (p):** point where principal axis intersects the image plane (origin of normalized coordinate system)
- Normalized coordinate system: origin is at the principal point
- Image coordinate system: origin is in the corner
- How to go from normalized coordinate system to image coordinate system?

Principal point offset

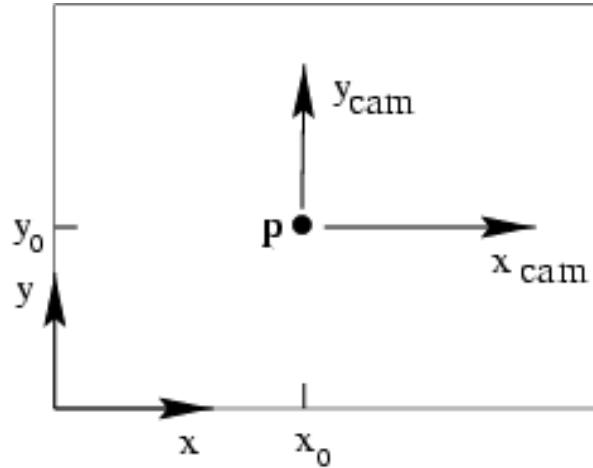

principal point: (p_x, p_y)

$$(X, Y, Z) \mapsto (fX/Z + p_x, fY/Z + p_y)$$

$$\begin{pmatrix} X \\ Y \\ Z \\ 1 \end{pmatrix} \mapsto \begin{pmatrix} fX + Zp_x \\ fY + Zp_y \\ Z \\ 1 \end{pmatrix} = \begin{bmatrix} f & p_x & 0 \\ f & p_y & 0 \\ 1 & 0 \end{bmatrix} \begin{pmatrix} X \\ Y \\ Z \\ 1 \end{pmatrix}$$

Principal point offset

principal point: (p_x, p_y)

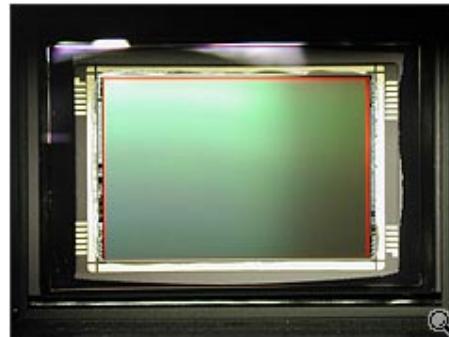

$$\begin{pmatrix} fX + Zp_x \\ fY + Zp_y \\ Z \end{pmatrix} = \begin{bmatrix} f & p_x \\ f & p_y \\ 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & X \\ 1 & 0 & Y \\ 1 & 0 & Z \\ 1 & 0 & 1 \end{bmatrix}$$

$$K = \begin{bmatrix} f & p_x \\ f & p_y \\ 1 \end{bmatrix}$$

calibration matrix

$$P = K[I | 0]$$

Pixel coordinates

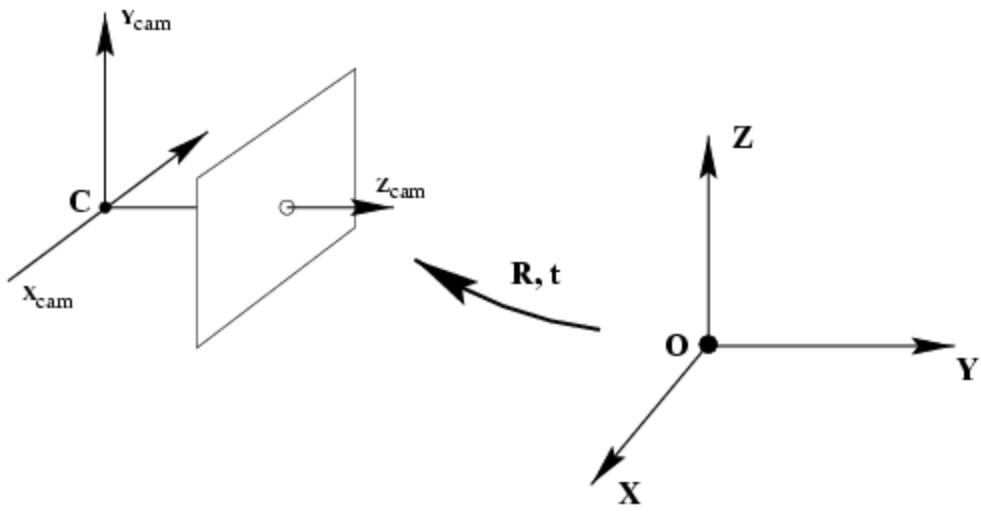

Pixel size: $\frac{1}{m_x} \times \frac{1}{m_y}$

- m_x pixels per meter in horizontal direction,
 m_y pixels per meter in vertical direction

$$K = \begin{bmatrix} m_x & & \\ & m_y & \\ & & 1 \end{bmatrix} \begin{bmatrix} f & p_x \\ & f & p_y \\ & & 1 \end{bmatrix} = \begin{bmatrix} \alpha_x & \beta_x \\ \alpha_y & \beta_y \\ & 1 \end{bmatrix}$$

pixels/m m pixels

Camera rotation and translation

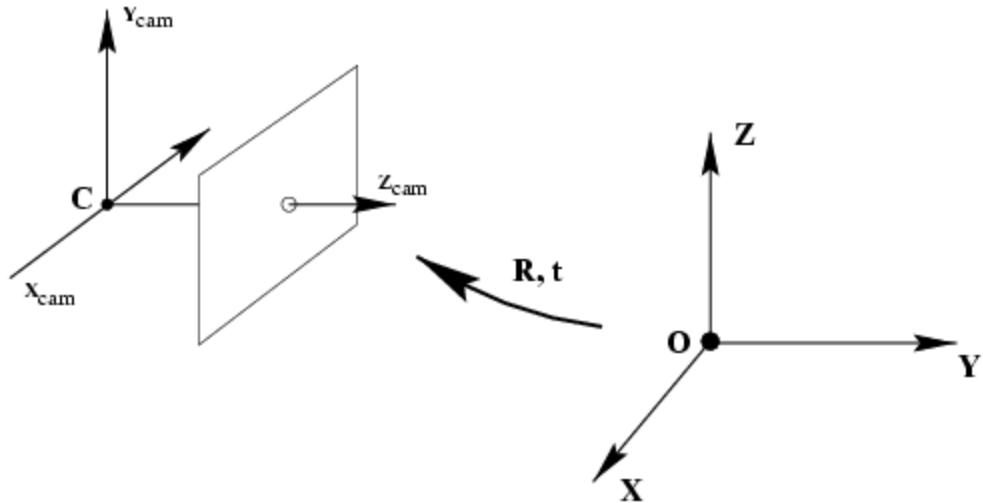

- In general, the camera coordinate frame will be related to the world coordinate frame by a rotation and a translation

$$\tilde{X}_{\text{cam}} = R(\tilde{X} - \tilde{C})$$

The diagram illustrates the transformation of a point from the world frame to the camera frame. It shows the equation $\tilde{X}_{\text{cam}} = R(\tilde{X} - \tilde{C})$. Four arrows point to the terms in the equation:

- An arrow points to \tilde{X}_{cam} labeled "coords. of point in camera frame".
- An arrow points to R labeled "coords. of a point in world frame (nonhomogeneous)".
- An arrow points to \tilde{X} labeled "coords. of a point in world frame (nonhomogeneous)".
- An arrow points to \tilde{C} labeled "coords. of camera center in world frame".

Camera rotation and translation

In non-homogeneous coordinates:

$$\tilde{X}_{\text{cam}} = R(\tilde{X} - \tilde{C})$$

$$X_{\text{cam}} = \begin{bmatrix} R & -R\tilde{C} \\ 0 & 1 \end{bmatrix} \begin{pmatrix} \tilde{X} \\ 1 \end{pmatrix} = \begin{bmatrix} R & -R\tilde{C} \\ 0 & 1 \end{bmatrix} X$$

$$x = K[I | 0]X_{\text{cam}} = K[R | -R\tilde{C}]X \quad P = K[R | t] \quad t = -R\tilde{C}$$

Note: C is the null space of the camera projection matrix (PC=0)

Camera parameters

- Intrinsic parameters

- Principal point coordinates
- Focal length
- Pixel magnification factors
- *Skew (non-rectangular pixels)*
- *Radial distortion*

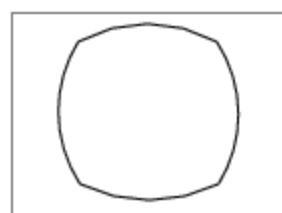

$$K = \begin{bmatrix} m_x & & \\ & m_y & \\ & & 1 \end{bmatrix} \begin{bmatrix} f & p_x \\ f & p_y \\ 1 & 1 \end{bmatrix} = \begin{bmatrix} \alpha_x & \beta_x \\ \alpha_y & \beta_y \\ 1 & 1 \end{bmatrix}$$

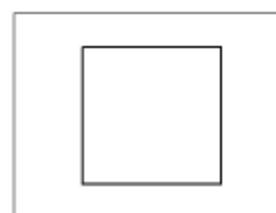

radial distortion

linear image

correction

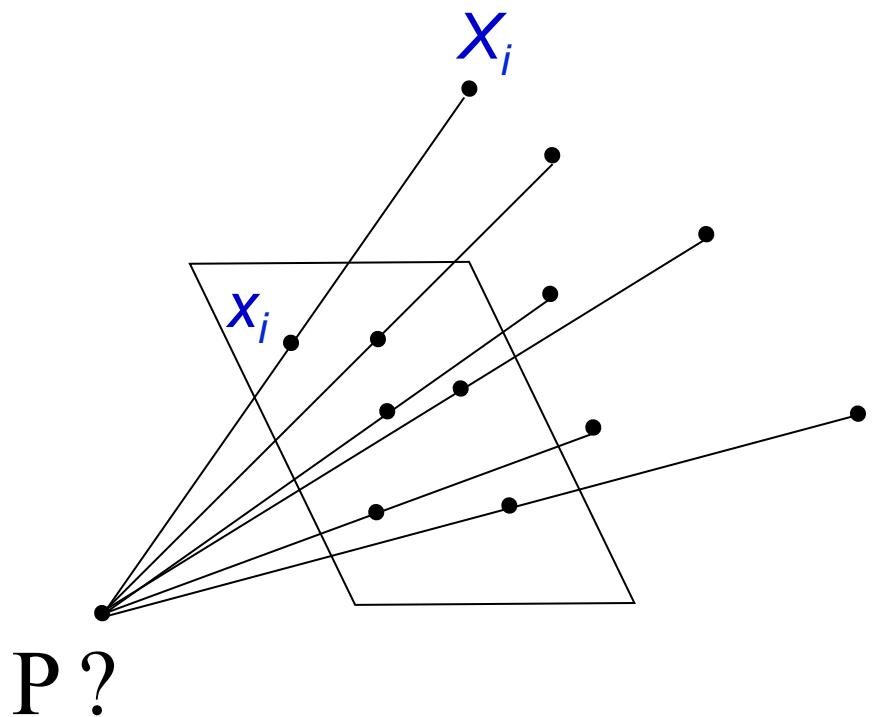

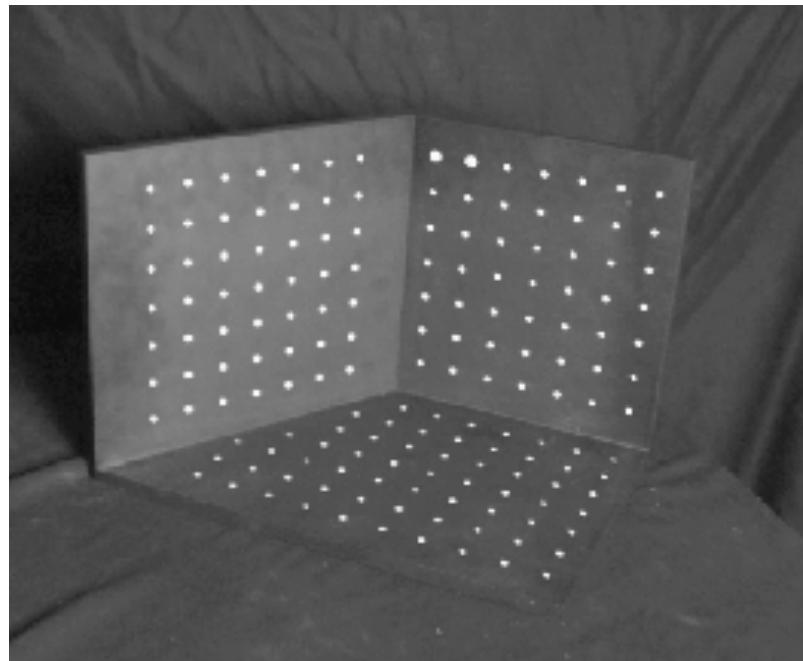

Camera parameters

- Intrinsic parameters
 - Principal point coordinates
 - Focal length
 - Pixel magnification factors
 - *Skew (non-rectangular pixels)*
 - *Radial distortion*
- Extrinsic parameters
 - Rotation and translation relative to world coordinate system

Camera calibration

- Given n points with known 3D coordinates X_i and known image projections x_i , estimate the camera parameters

Camera calibration

$$\lambda \mathbf{x}_i = \mathbf{P} \mathbf{X}_i$$

$$\mathbf{x}_i \times \mathbf{P} \mathbf{X}_i = 0$$

$$\begin{bmatrix} x_i \\ y_i \\ 1 \end{bmatrix} \times \begin{bmatrix} \mathbf{P}_1^T \mathbf{X}_i \\ \mathbf{P}_2^T \mathbf{X}_i \\ \mathbf{P}_3^T \mathbf{X}_i \end{bmatrix} = 0$$

12 long vector or row, 4 each in each

12 long vector, 4 each concated on there

$$\begin{bmatrix} 0 & -\mathbf{X}_i^T & y_i \mathbf{X}_i^T \\ \mathbf{X}_i^T & 0 & -x_i \mathbf{X}_i^T \\ -y_i \mathbf{X}_i^T & x_i \mathbf{X}_i^T & 0 \end{bmatrix} \begin{pmatrix} \mathbf{P}_1 \\ \mathbf{P}_2 \\ \mathbf{P}_3 \end{pmatrix} = 0$$

Two linearly independent equations

Camera calibration

$$\begin{bmatrix} 0^T & X_1^T & -y_1 X_1^T \\ X_1^T & 0^T & -x_1 X_1^T \\ \dots & \dots & \dots \\ 0^T & X_n^T & -y_n X_n^T \\ X_n^T & 0^T & -x_n X_n^T \end{bmatrix} \begin{pmatrix} P_1 \\ P_2 \\ P_3 \end{pmatrix} = 0 \quad Ap = 0$$

- P has 11 degrees of freedom (12 parameters, but scale is arbitrary)
- One 2D/3D correspondence gives us two linearly independent equations
- Homogeneous least squares
- 6 correspondences needed for a minimal solution

Camera calibration

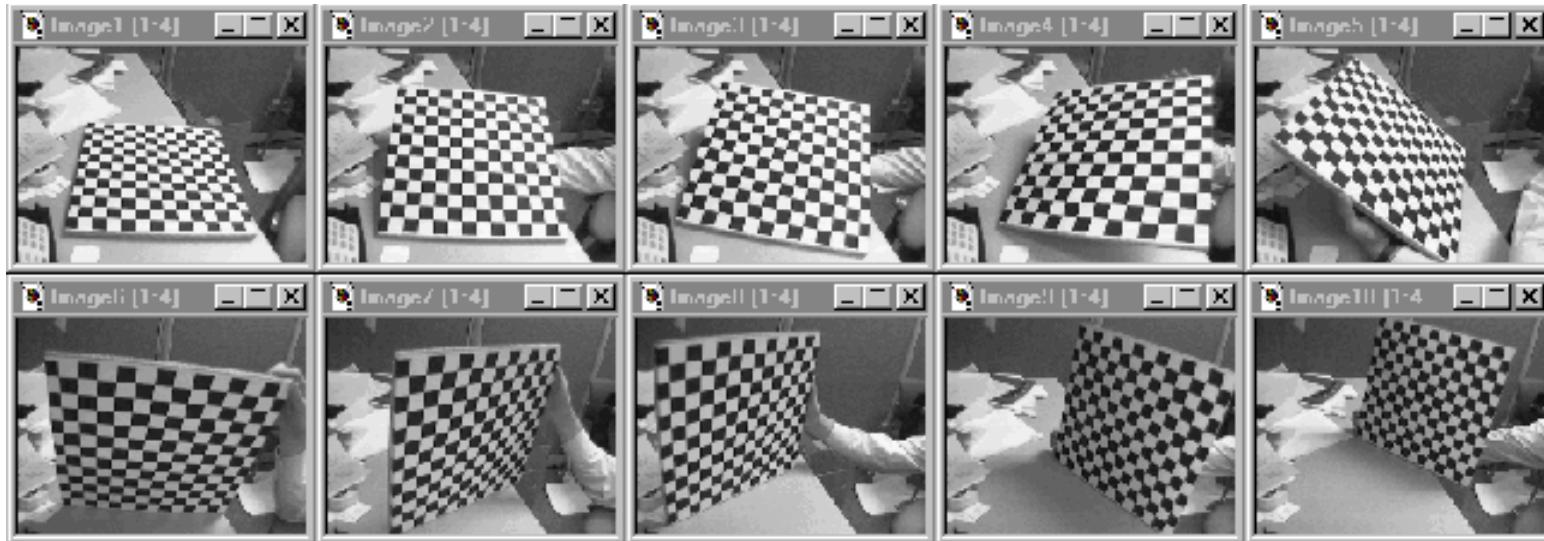

$$\begin{bmatrix} 0^T & X_1^T & -y_1 X_1^T \\ X_1^T & 0^T & -x_1 X_1^T \\ \dots & \dots & \dots \\ 0^T & X_n^T & -y_n X_n^T \\ X_n^T & 0^T & -x_n X_n^T \end{bmatrix} \begin{pmatrix} P_1 \\ P_2 \\ P_3 \end{pmatrix} = 0 \quad Ap = 0$$

- Note: for coplanar points that satisfy $\Pi^T X = 0$, we will get degenerate solutions $(\Pi, 0, 0)$, $(0, \Pi, 0)$, or $(0, 0, \Pi)$

Camera calibration

- Once we've recovered the numerical form of the camera matrix, we still have to figure out the intrinsic and extrinsic parameters
- This is a matrix decomposition problem, not an estimation problem (see F&P sec. 3.2, 3.3)

Alternative: multi-plane calibration

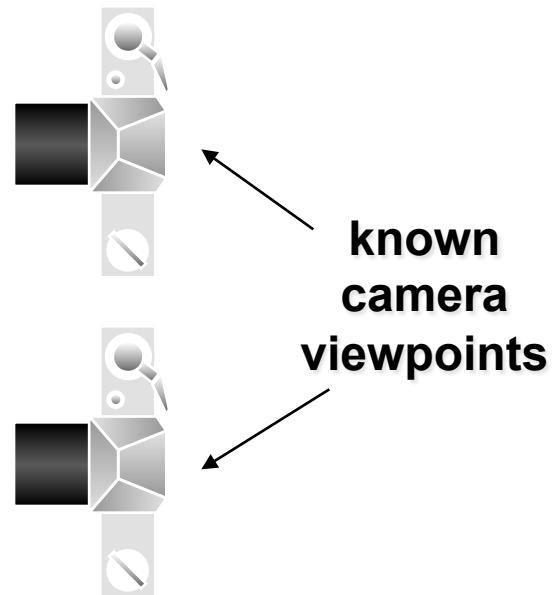

Images courtesy Jean-Yves Bouguet, Intel Corp.

Advantage

- Only requires a plane
- Don't have to know positions/orientations
- Good code available online!
 - Intel's OpenCV library: <http://www.intel.com/research/mrl/research/opencv/>
 - Matlab version by Jean-Yves Bouguet:

Stereo Reconstruction

Shape (3D) from two (or more) images

Example

images

shape

surface
reflectance

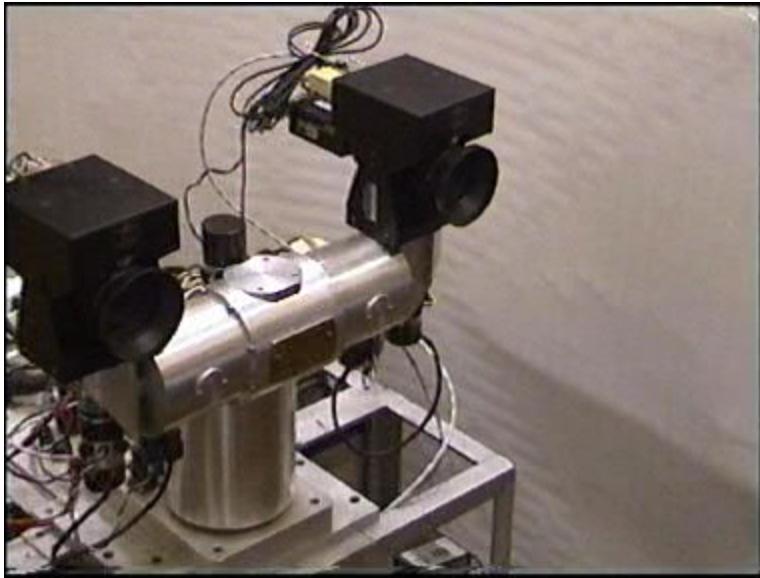

Scenarios

The two images can arise from

- A stereo rig consisting of two cameras
 - the two images are acquired **simultaneously**
- A single moving camera (static scene)
 - the two images are acquired **sequentially**

The two scenarios are geometrically equivalent

Stereo head

Camera on a mobile vehicle

(COURTESY SONY)

The objective

Given two images of a scene acquired by known cameras compute the 3D position of the scene (structure recovery)

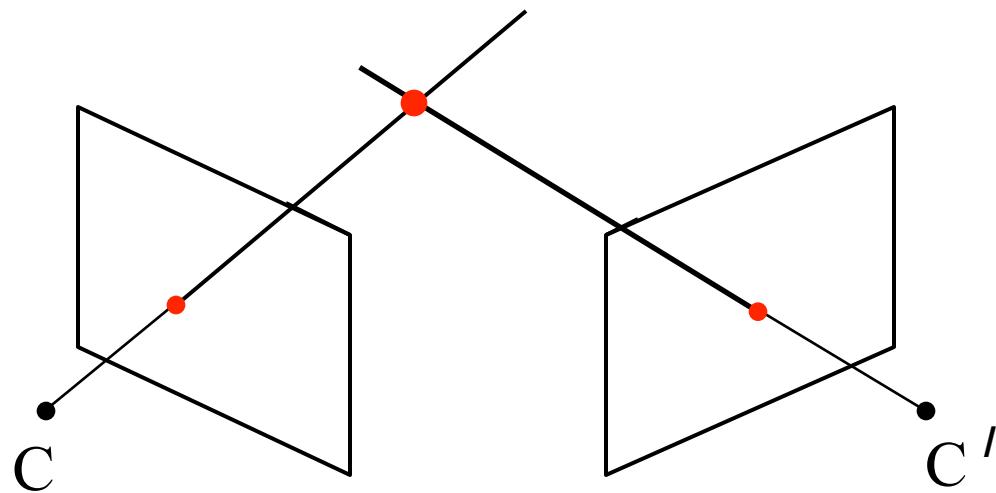

Basic principle: triangulate from corresponding image points

- Determine 3D point at intersection of two back-projected rays

Corresponding points are images of the same scene point

Triangulation

The back-projected points generate rays which intersect at the 3D scene point

An algorithm for stereo reconstruction

1. For each point in the first image determine the corresponding point in the second image
(this is a search problem)

2. For each pair of matched points determine the 3D point by triangulation
(this is an estimation problem)

The correspondence problem

Given a point x in one image find the corresponding point in the other image

This appears to be a 2D search problem, but it is reduced to a 1D search by the **epipolar constraint**

Outline

1. Epipolar geometry

- the geometry of two cameras
- reduces the correspondence problem to a line search

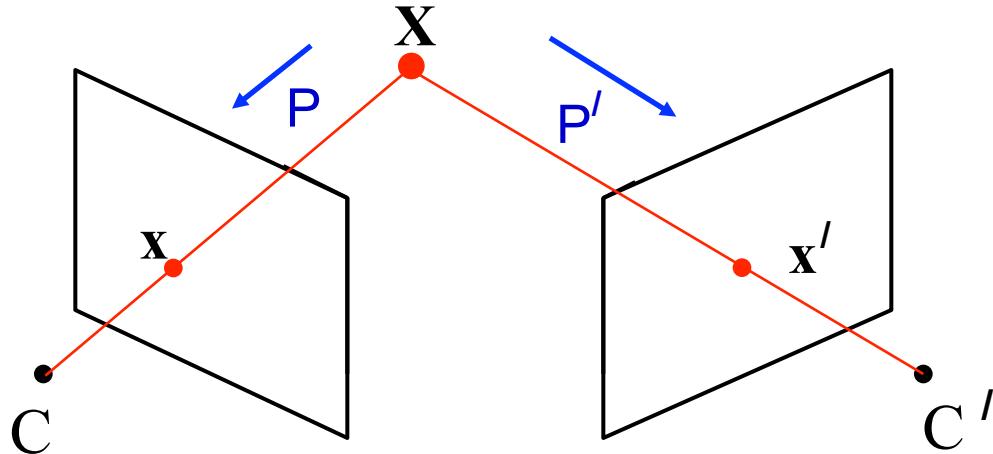

2. Stereo correspondence algorithms

3. Triangulation

Notation

The two cameras are P and P' , and a 3D point \mathbf{X} is imaged as

$$\mathbf{x} = P\mathbf{X} \quad \mathbf{x}' = P'\mathbf{X}$$

P : 3×4 matrix

\mathbf{X} : 4-vector

\mathbf{x} : 3-vector

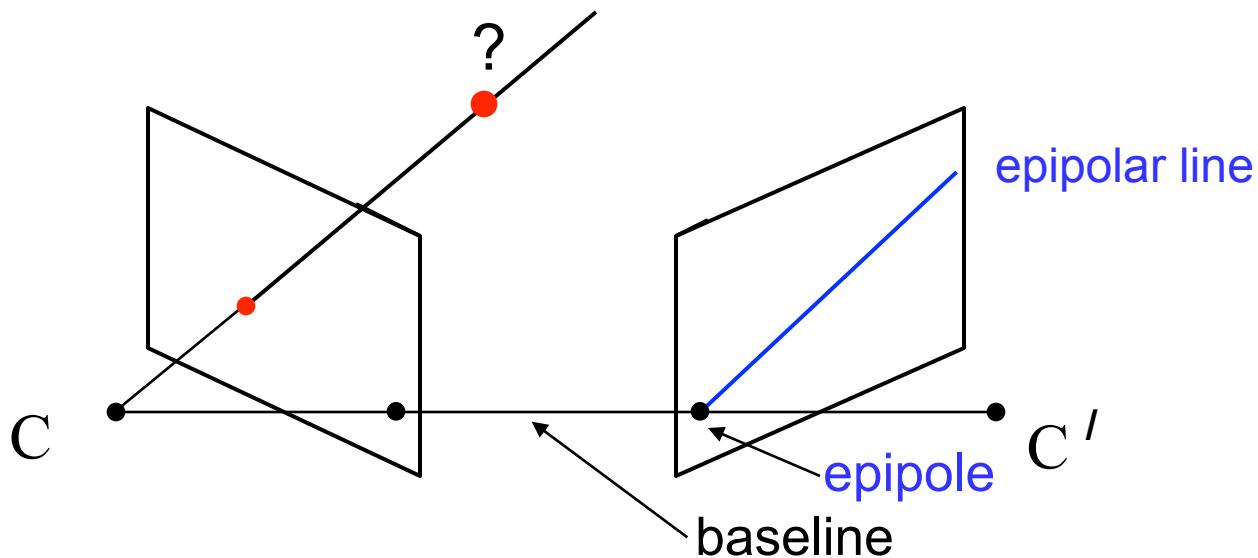

Warning

for equations involving homogeneous quantities '=' means 'equal up to scale'

Epipolar geometry

Epipolar geometry

Given an image point in one view, where is the corresponding point in the other view?

- A point in one view “generates” an **epipolar line** in the other view
- The corresponding point lies on this line

Epipolar line

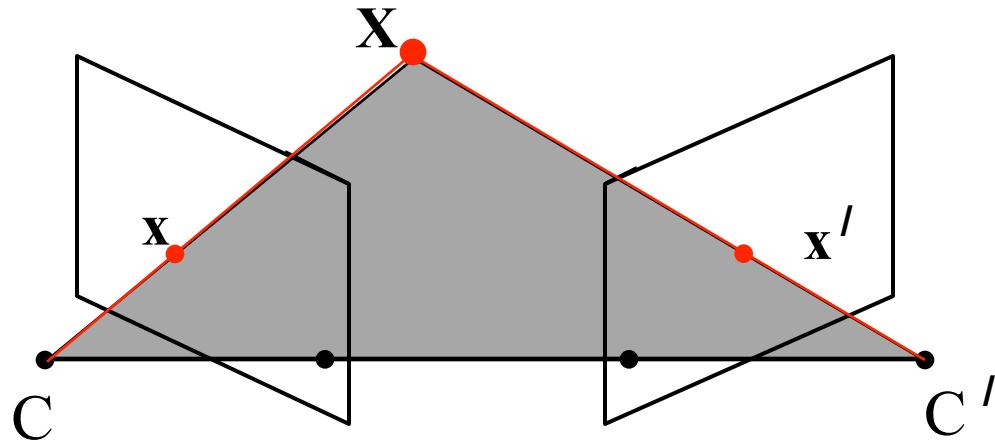

Epipolar constraint

- Reduces correspondence problem to 1D search along an epipolar line

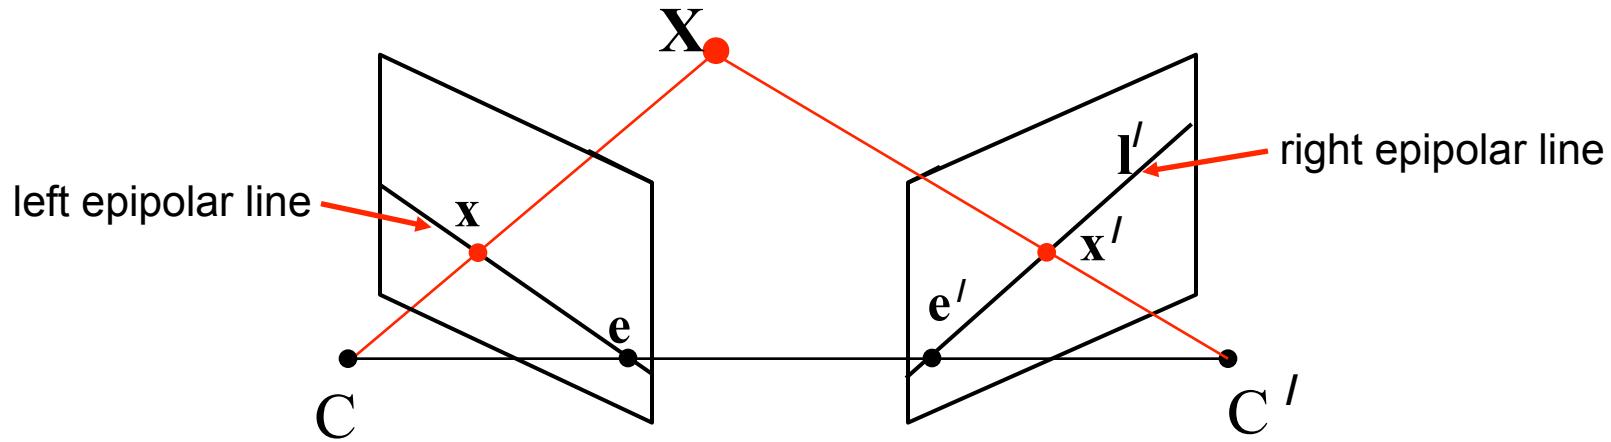

Epipolar geometry continued

Epipolar geometry is a consequence of the **coplanarity** of the camera centres and scene point

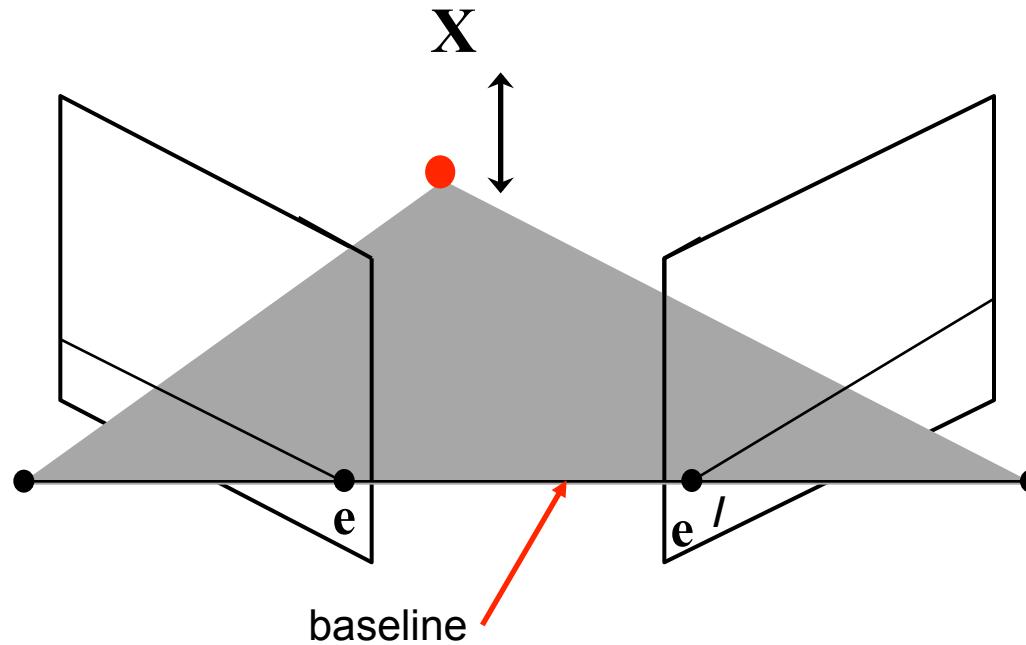

The camera centres, corresponding points and scene point lie in a single plane, known as the **epipolar plane**

Nomenclature

- The **epipolar line \mathbf{l}'** is the image of the ray through \mathbf{x}
- The **epipole \mathbf{e}** is the point of intersection of the line joining the camera centres with the image plane
 - this line is the **baseline** for a stereo rig, and
 - the translation vector for a moving camera
- The epipole is the image of the centre of the other camera: $\mathbf{e} = \mathbf{P}\mathbf{C}'$, $\mathbf{e}' = \mathbf{P}'\mathbf{C}$

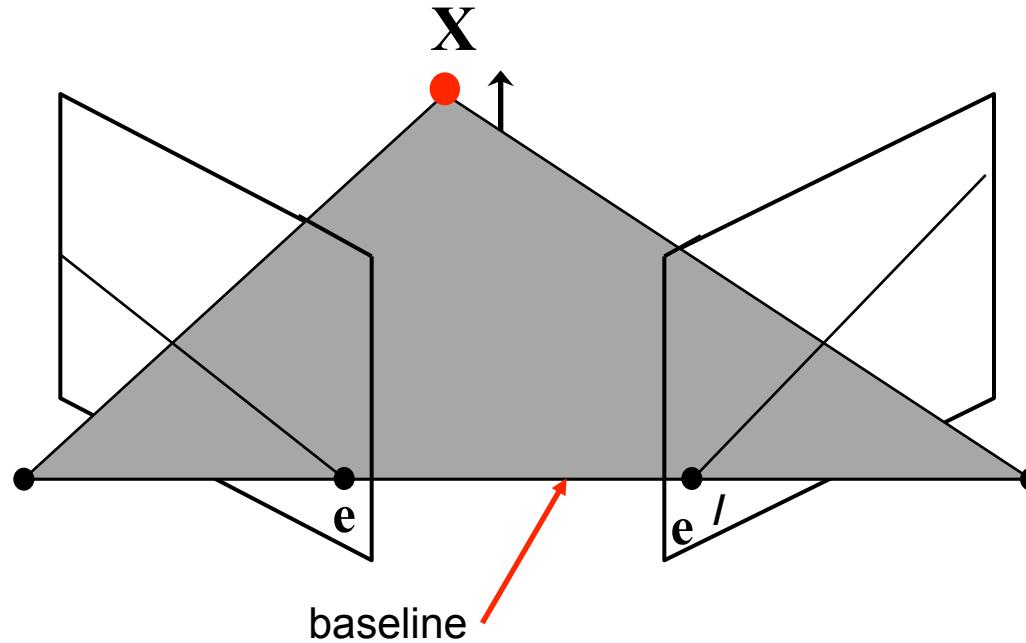

The epipolar pencil

As the position of the 3D point \mathbf{X} varies, the epipolar planes “rotate” about the baseline. This family of planes is known as an **epipolar pencil**. All epipolar lines intersect at the epipole.

(a pencil is a one parameter family)

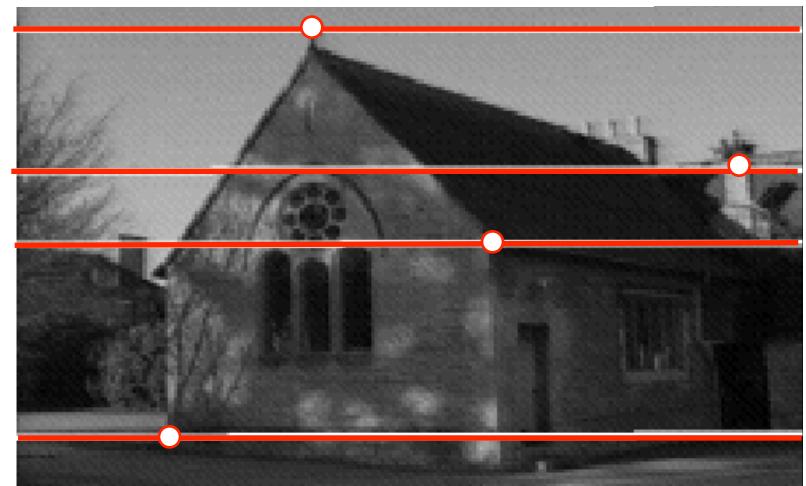

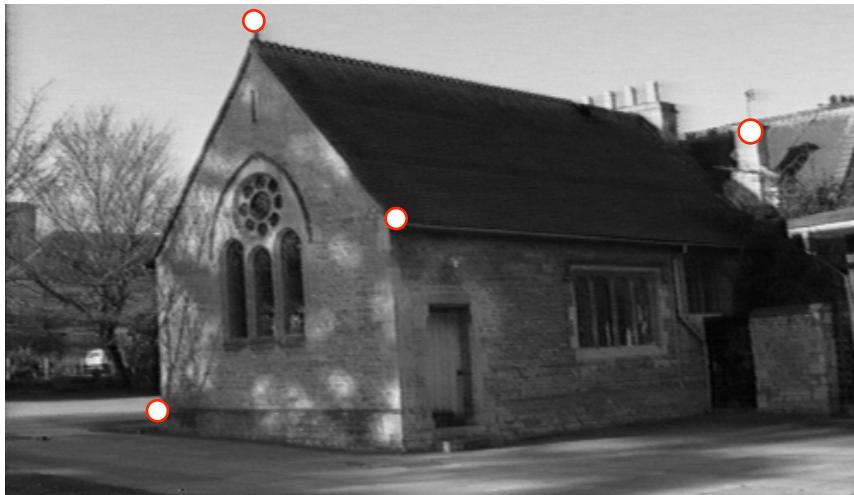

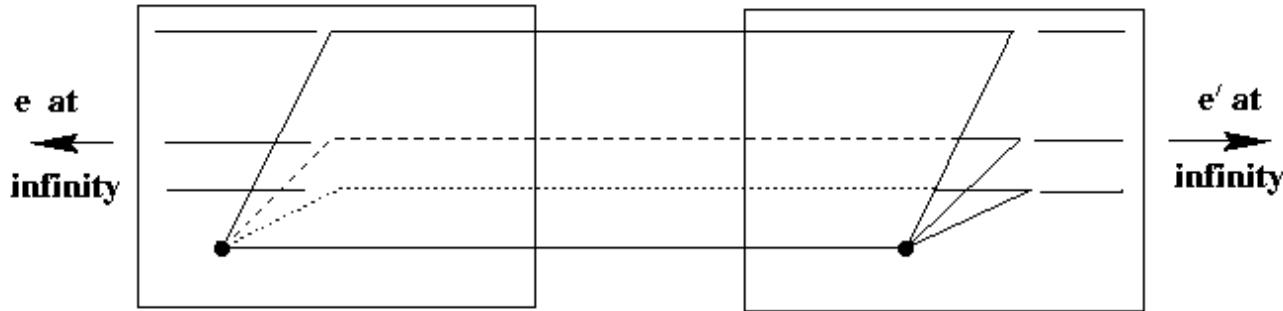

The epipolar pencil

As the position of the 3D point \mathbf{X} varies, the epipolar planes “rotate” about the baseline. This family of planes is known as an **epipolar pencil**. All epipolar lines intersect at the epipole.

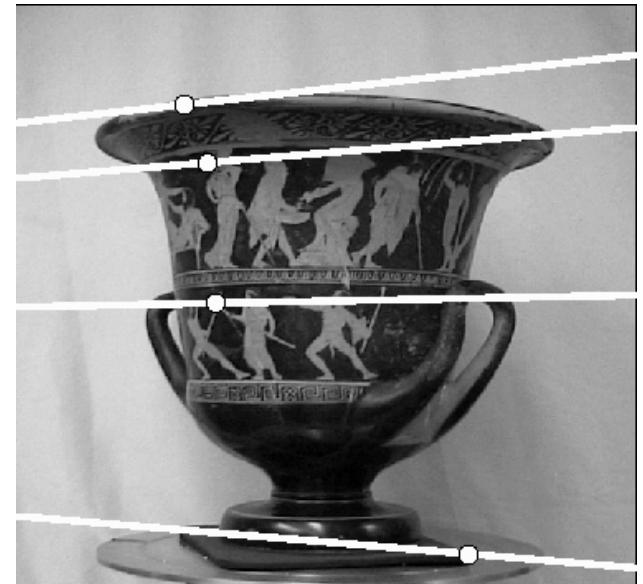

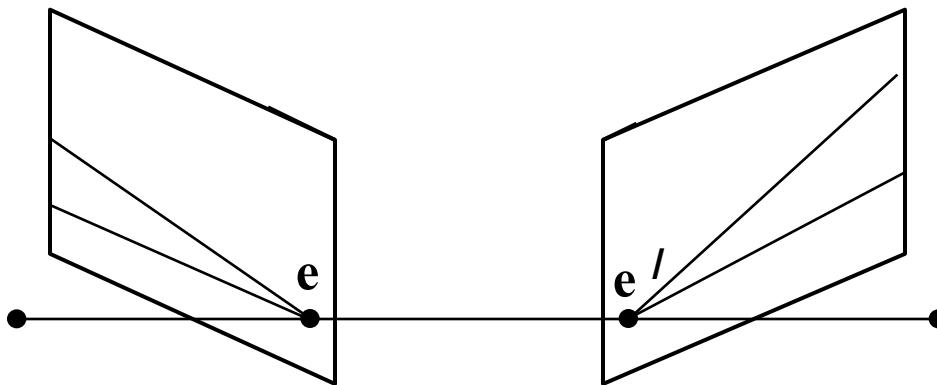

(a pencil is a one parameter family)

Epipolar geometry example I: parallel cameras

Epipolar geometry depends **only** on the relative pose (position and orientation) and internal parameters of the two cameras, i.e. the position of the camera centres and image planes. It does **not** depend on the scene structure (3D points external to the camera).

Epipolar geometry example II: converging cameras

Note, epipolar lines are in general **not** parallel

Homogeneous notation for lines

Recall that a point (x, y) in 2D is represented by the homogeneous 3-vector $\mathbf{x} = (x_1, x_2, x_3)^\top$, where $x = x_1/x_3, y = x_2/x_3$

A [line](#) in 2D is represented by the homogeneous 3-vector

$$\mathbf{l} = \begin{pmatrix} l_1 \\ l_2 \\ l_3 \end{pmatrix}$$

which is the line $l_1x + l_2y + l_3 = 0$.

[Example](#) represent the line $y = 1$ as a homogeneous vector.

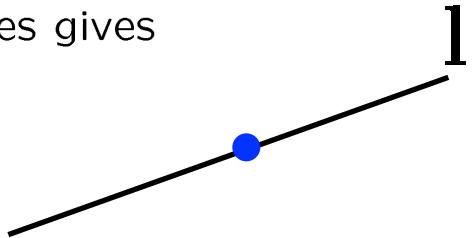

Write the line as $-y + 1 = 0$ then $l_1 = 0, l_2 = -1, l_3 = 1$, and $\mathbf{l} = (0, -1, 1)^\top$.

Note that $\mu(l_1x + l_2y + l_3) = 0$ represents the same line (only the ratio of the homogeneous line coordinates is significant).

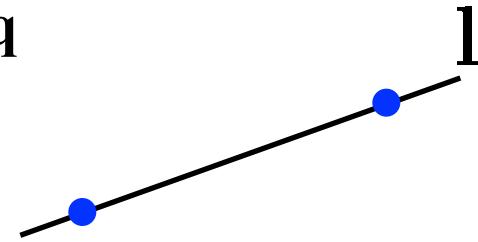

Writing both the point and line in homogeneous coordinates gives

$$l_1x_1 + l_2x_2 + l_3x_3 = 0$$

- [point on line](#) $\mathbf{l} \cdot \mathbf{x} = 0$ or $\mathbf{l}^\top \mathbf{x} = 0$ or $\mathbf{x}^\top \mathbf{l} = 0$

- The line \mathbf{l} through the two points \mathbf{p} and \mathbf{q} is $\mathbf{l} = \mathbf{p} \times \mathbf{q}$

Proof

$$\mathbf{l} \cdot \mathbf{p} = (\mathbf{p} \times \mathbf{q}) \cdot \mathbf{p} = 0 \quad \mathbf{l} \cdot \mathbf{q} = (\mathbf{p} \times \mathbf{q}) \cdot \mathbf{q} = 0$$

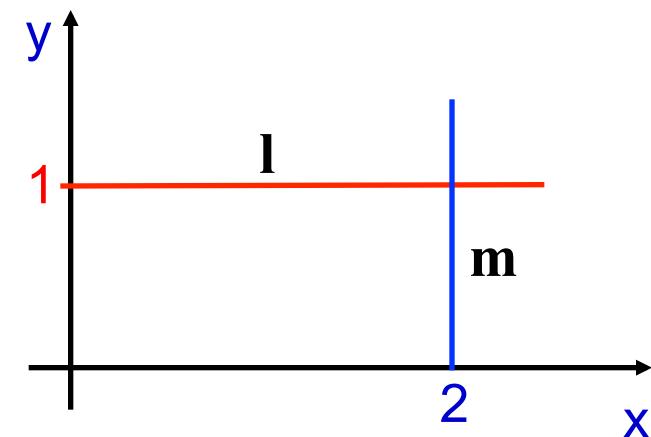

- The intersection of two lines \mathbf{l} and \mathbf{m} is the point $\mathbf{x} = \mathbf{l} \times \mathbf{m}$

Example: compute the point of intersection of the two lines \mathbf{l} and \mathbf{m} in the figure below

$$\mathbf{l} = \begin{pmatrix} 0 \\ -1 \\ 1 \end{pmatrix} \quad \mathbf{m} = \begin{pmatrix} -1 \\ 0 \\ 2 \end{pmatrix}$$

$$\mathbf{x} = \mathbf{l} \times \mathbf{m} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & -1 & 1 \\ -1 & 0 & 2 \end{vmatrix} = \begin{pmatrix} -2 \\ -1 \\ -1 \end{pmatrix}$$

which is the point $(2, 1)$

Matrix representation of the vector cross product

The vector product $\mathbf{v} \times \mathbf{x}$ can be represented as a matrix multiplication

$$\mathbf{v} \times \mathbf{x} = \begin{pmatrix} v_2x_3 - v_3x_2 \\ v_3x_1 - v_1x_3 \\ v_1x_2 - v_2x_1 \end{pmatrix} = [\mathbf{v}]_{\times}\mathbf{x}$$

where

$$[\mathbf{v}]_{\times} = \begin{bmatrix} 0 & -v_3 & v_2 \\ v_3 & 0 & -v_1 \\ -v_2 & v_1 & 0 \end{bmatrix}$$

- $[\mathbf{v}]_{\times}$ is a 3×3 skew-symmetric matrix of rank 2.
- \mathbf{v} is the null-vector of $[\mathbf{v}]_{\times}$, since $\mathbf{v} \times \mathbf{v} = [\mathbf{v}]_{\times}\mathbf{v} = \mathbf{0}$.

Example: compute the cross product of \mathbf{l} and \mathbf{m}

$$\mathbf{l} = \begin{pmatrix} 0 \\ -1 \\ 1 \end{pmatrix} \quad \mathbf{m} = \begin{pmatrix} -1 \\ 0 \\ 2 \end{pmatrix} \quad [\mathbf{v}]_{\times} = \begin{bmatrix} 0 & -v_3 & v_2 \\ v_3 & 0 & -v_1 \\ -v_2 & v_1 & 0 \end{bmatrix}$$

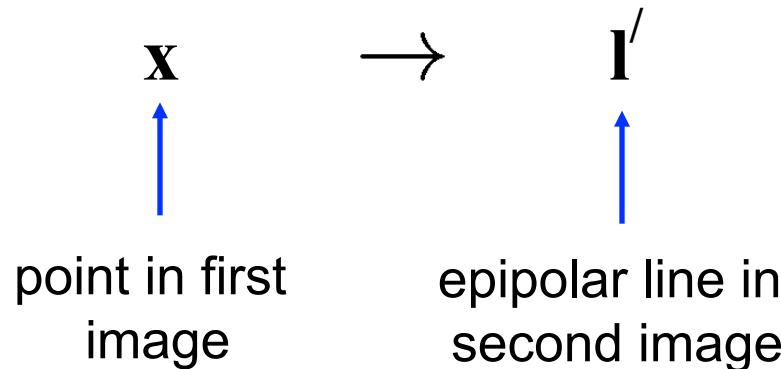

$$\mathbf{x} = \mathbf{l} \times \mathbf{m} = [\mathbf{l}]_{\times} \mathbf{m} = \begin{bmatrix} 0 & -1 & -1 \\ 1 & 0 & 0 \\ 1 & 0 & 0 \end{bmatrix} \begin{pmatrix} -1 \\ 0 \\ 2 \end{pmatrix} = \begin{pmatrix} -2 \\ -1 \\ -1 \end{pmatrix}$$

Note

$$\begin{bmatrix} 0 & -1 & -1 \\ 1 & 0 & 0 \\ 1 & 0 & 0 \end{bmatrix} \begin{pmatrix} 0 \\ -1 \\ 1 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

Algebraic representation of epipolar geometry

We know that the epipolar geometry defines a mapping

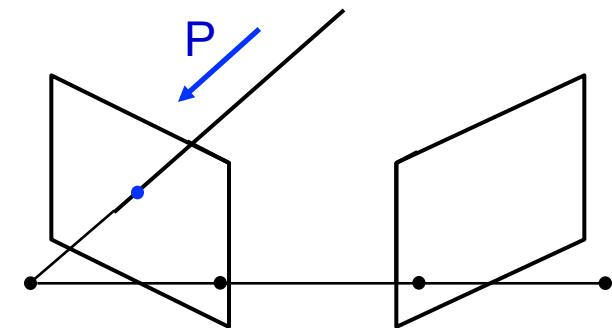

- the map only depends on the cameras P, P' (not on structure)
- it will be shown that the map is linear and can be written as $\mathbf{l}' = F\mathbf{x}$, where F is a 3×3 matrix called the fundamental matrix

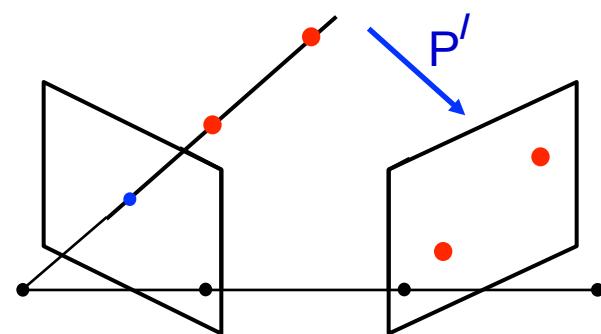

Derivation of the algebraic expression $\mathbf{l}' = \mathbf{F}\mathbf{x}$

Outline

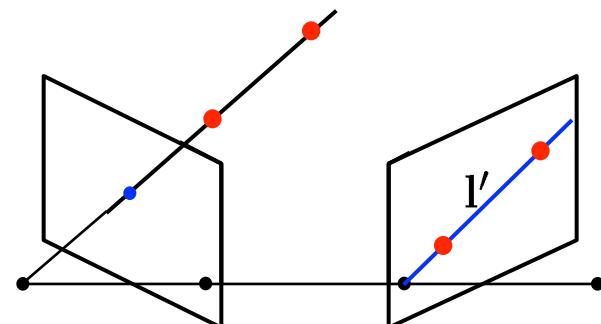

Step 1: for a point x in the first image
back project a ray with camera P

Step 2: choose two points on the ray and
project into the second image with camera P'

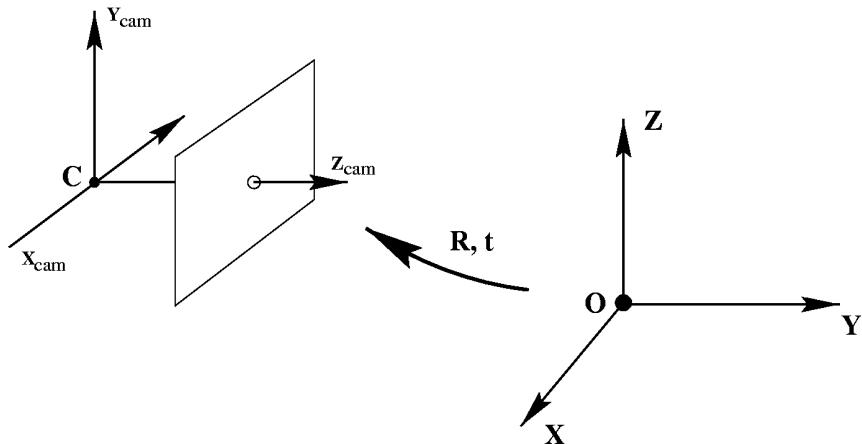

Step 3: compute the line through the two
image points using the relation $\mathbf{l}' = \mathbf{p} \times \mathbf{q}$

- choose camera matrices

$$P = K [R \mid t]$$

internal calibration rotation translation
 from world to camera coordinate frame

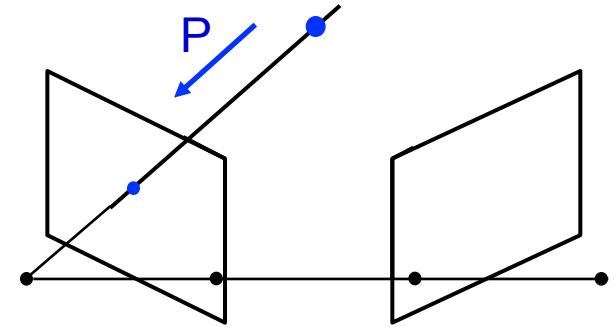

- first camera $P = K [I \mid 0]$

world coordinate frame aligned with first camera

- second camera $P' = K' [R \mid t]$

Step 1: for a point x in the first image
back project a ray with camera $P = K [I \mid 0]$

A point x back projects to a ray

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} = zK^{-1} \begin{pmatrix} x \\ y \\ 1 \end{pmatrix} = zK^{-1}x$$

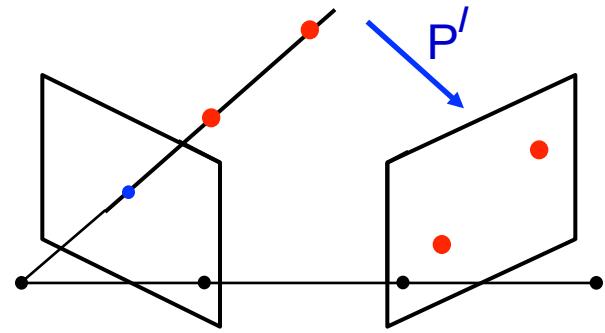

where Z is the point's depth, since

$$x(z) = \begin{pmatrix} zK^{-1}x \\ 1 \end{pmatrix}$$

satisfies

$$PX(z) = K[I \mid 0]x(z) = x$$

Step 2: choose two points on the ray and project into the second image with camera P'

Consider two points on the ray $X(z) = \begin{pmatrix} zK^{-1}\mathbf{x} \\ 1 \end{pmatrix}$

- $Z = 0$ is the camera centre $\begin{pmatrix} \mathbf{0} \\ 1 \end{pmatrix}$

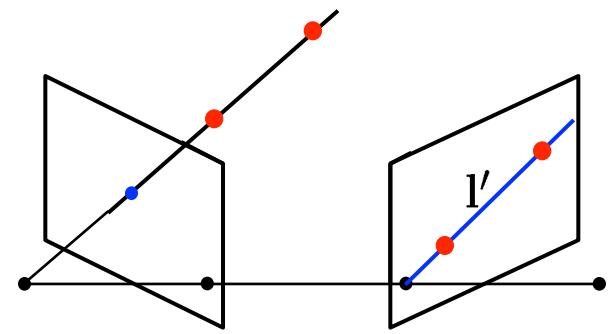

- $Z = \infty$ is the point at infinity $\begin{pmatrix} K^{-1}\mathbf{x} \\ 0 \end{pmatrix}$

Project these two points into the second view

$$P' \begin{pmatrix} \mathbf{0} \\ 1 \end{pmatrix} = K'[R \mid t] \begin{pmatrix} \mathbf{0} \\ 1 \end{pmatrix} = K'\mathbf{t}$$

$$P' \begin{pmatrix} K^{-1}\mathbf{x} \\ 0 \end{pmatrix} = K'[R \mid t] \begin{pmatrix} K^{-1}\mathbf{x} \\ 0 \end{pmatrix} = K'R K^{-1}\mathbf{x}$$

Step 3: compute the line through the two image points using the relation $\mathbf{l}' = \mathbf{p} \times \mathbf{q}$

Compute the line through the points $\mathbf{l}' = (\mathbf{K}'\mathbf{t}) \times (\mathbf{K}'\mathbf{R}\mathbf{K}^{-1}\mathbf{x})$

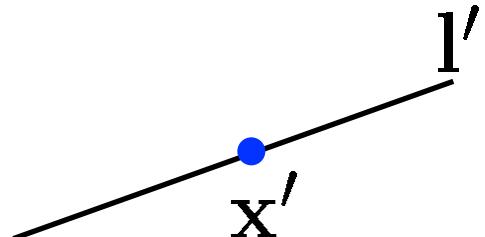

Using the identity $(\mathbf{M}\mathbf{a}) \times (\mathbf{M}\mathbf{b}) = \mathbf{M}^{-\top}(\mathbf{a} \times \mathbf{b})$ where $\mathbf{M}^{-\top} = (\mathbf{M}^{-1})^\top = (\mathbf{M}^\top)^{-1}$

$$\mathbf{l}' = \mathbf{K}'^{-\top} \left(\mathbf{t} \times (\mathbf{R}\mathbf{K}^{-1}\mathbf{x}) \right) = \underbrace{\mathbf{K}'^{-\top} [\mathbf{t}]_\times \mathbf{R}\mathbf{K}^{-1}}_{\mathbf{F}} \mathbf{x} \quad \mathbf{F} \text{ is the fundamental matrix}$$

$$\mathbf{l}' = \mathbf{F}\mathbf{x} \quad \mathbf{F} = \mathbf{K}'^{-\top} [\mathbf{t}]_\times \mathbf{R}\mathbf{K}^{-1}$$

Points \mathbf{x} and \mathbf{x}' correspond ($\mathbf{x} \leftrightarrow \mathbf{x}'$) then $\mathbf{x}'^\top \mathbf{l}' = 0$

$$\mathbf{x}'^\top \mathbf{F}\mathbf{x} = 0$$

Example I: compute the fundamental matrix for a parallel camera stereo rig

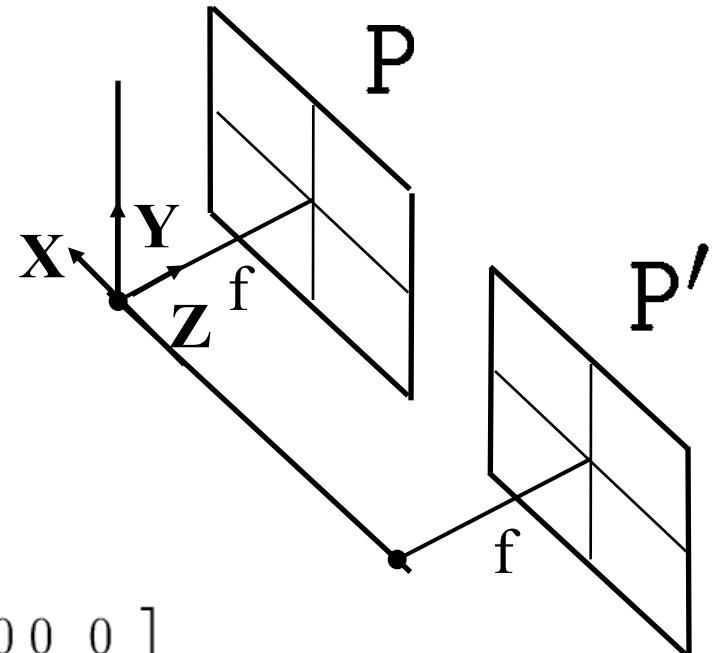

$$P = K[I \mid \mathbf{0}] \quad P' = K'[R \mid t]$$

$$K = K' = \begin{bmatrix} f & 0 & 0 \\ 0 & f & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad R = I \quad t = \begin{pmatrix} t_x \\ 0 \\ 0 \end{pmatrix}$$

$$F = K'^{-\top}[t]_x R K^{-1}$$

$$= \begin{bmatrix} 1/f & 0 & 0 \\ 0 & 1/f & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & -t_x \\ 0 & t_x & 0 \end{bmatrix} \begin{bmatrix} 1/f & 0 & 0 \\ 0 & 1/f & 0 \\ 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix}$$

$$\mathbf{x}'^\top F \mathbf{x} = (x' \ y' \ 1) \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix} \begin{pmatrix} x \\ y \\ 1 \end{pmatrix} = 0$$

- reduces to $y = y'$, i.e. raster correspondence (horizontal scan-lines)

F is a rank 2 matrix

The epipole e is the null-space vector (kernel) of F (exercise), i.e. $Fe = 0$

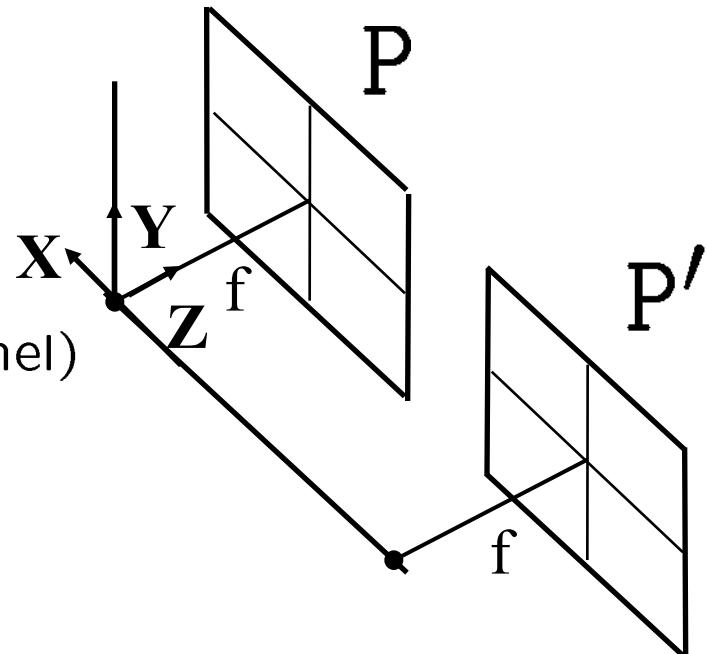

In this case

$$\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix} \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} = 0$$

so that

$$e = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}$$

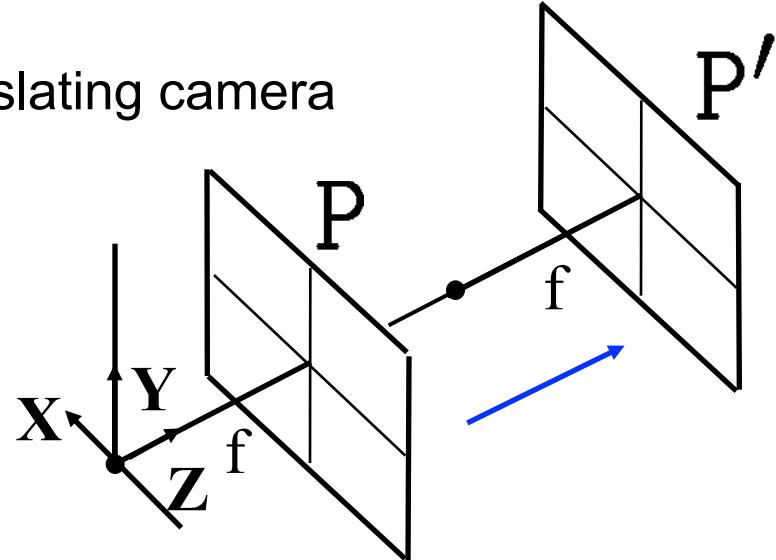

Geometric interpretation ?

Example II: compute F for a forward translating camera

$$P = K[I \mid \mathbf{0}] \quad P' = K'[R \mid t]$$

$$K = K' = \begin{bmatrix} f & 0 & 0 \\ 0 & f & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad R = I \quad t = \begin{pmatrix} 0 \\ 0 \\ t_z \end{pmatrix}$$

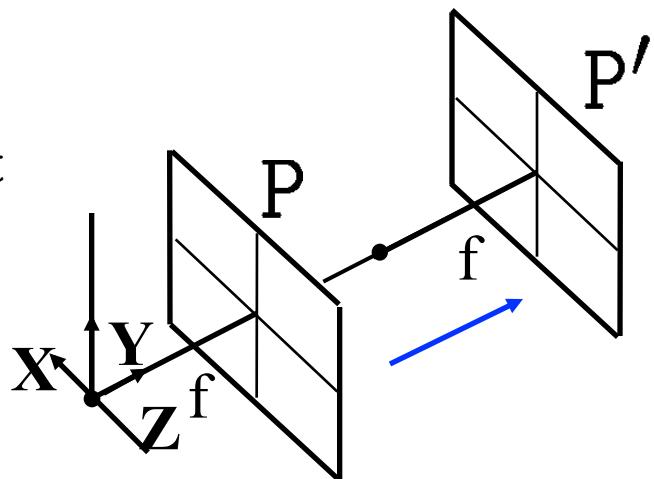

$$F = K'^{-T}[t] \times R K^{-1}$$

$$\begin{aligned}
 &= \begin{bmatrix} 1/f & 0 & 0 \\ 0 & 1/f & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 & -t_z & 0 \\ t_z & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 1/f & 0 & 0 \\ 0 & 1/f & 0 \\ 0 & 0 & 1 \end{bmatrix} \\
 &= \begin{bmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}
 \end{aligned}$$

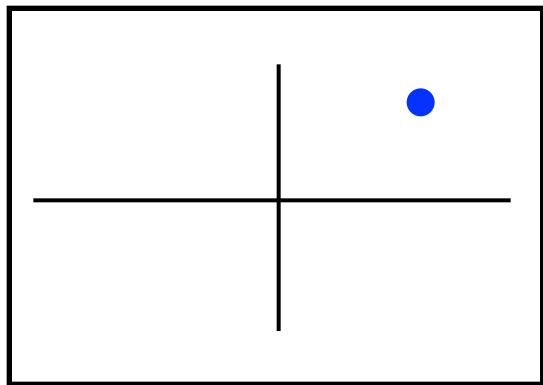

From $\mathbf{l}' = \mathbf{F}\mathbf{x}$ the epipolar line for the point $\mathbf{x} = (x, y, 1)^\top$ is

$$\mathbf{l}' = \begin{bmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{pmatrix} x \\ y \\ 1 \end{pmatrix} = \begin{pmatrix} -y \\ x \\ 0 \end{pmatrix}$$

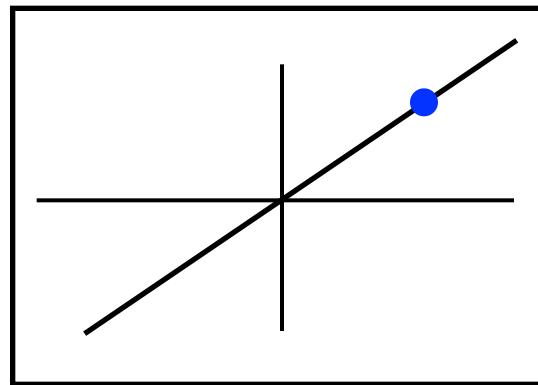

The points $(x, y, 1)^\top$ and $(0, 0, 1)^\top$ lie on this line

first image

second image

Summary: Properties of the Fundamental matrix

- F is a rank 2 homogeneous matrix with 7 degrees of freedom.
- Point correspondence:
if x and x' are corresponding image points, then
 $x'^T F x = 0$.
- Epipolar lines:
 - ◊ $l' = Fx$ is the epipolar line corresponding to x .
 - ◊ $l = F^T x'$ is the epipolar line corresponding to x' .
- Epipoles:
 - ◊ $F\mathbf{e} = \mathbf{0}$.
 - ◊ $F^T \mathbf{e}' = \mathbf{0}$.
- Computation from camera matrices P, P' :
 $P = K[I \mid \mathbf{0}], P' = K'[R \mid \mathbf{t}], F = K'^{-T}[t]_x R K^{-1}$

Stereo correspondence algorithms

Problem statement

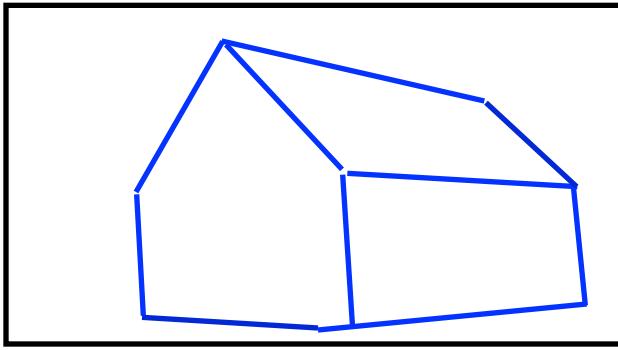

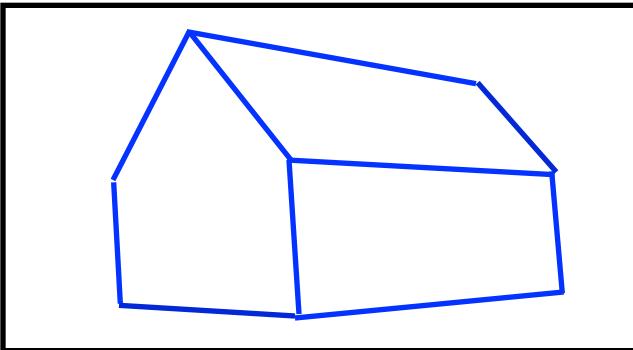

Given: two images and their associated cameras compute corresponding image points.

Algorithms may be classified into two types:

1. Dense: compute a correspondence at every pixel
2. Sparse: compute correspondences only for features

The methods may be top down or bottom up

Top down matching

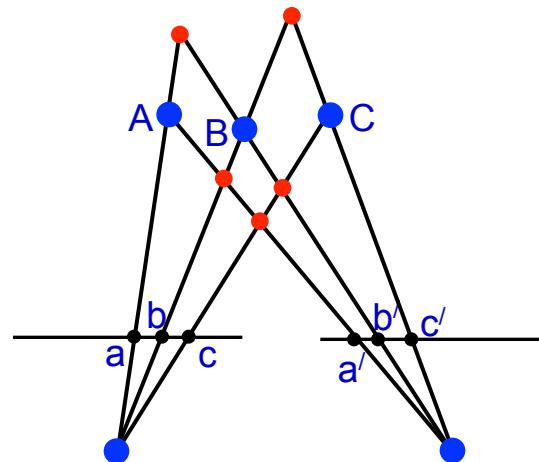

1. Group model (house, windows, etc) independently in each image
2. Match points (vertices) between images

Bottom up matching

- epipolar geometry reduces the correspondence search from 2D to a 1D search on corresponding epipolar lines

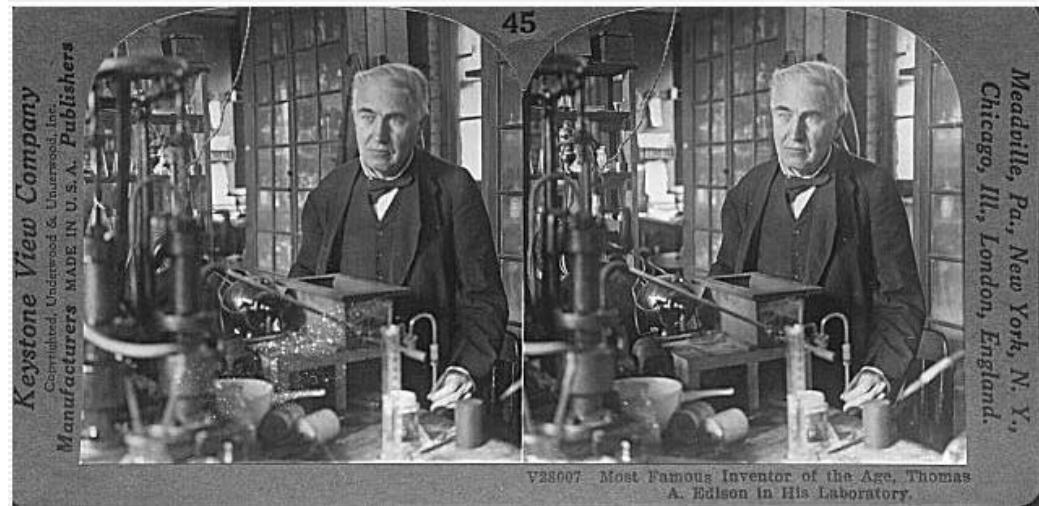

- 1D correspondence problem

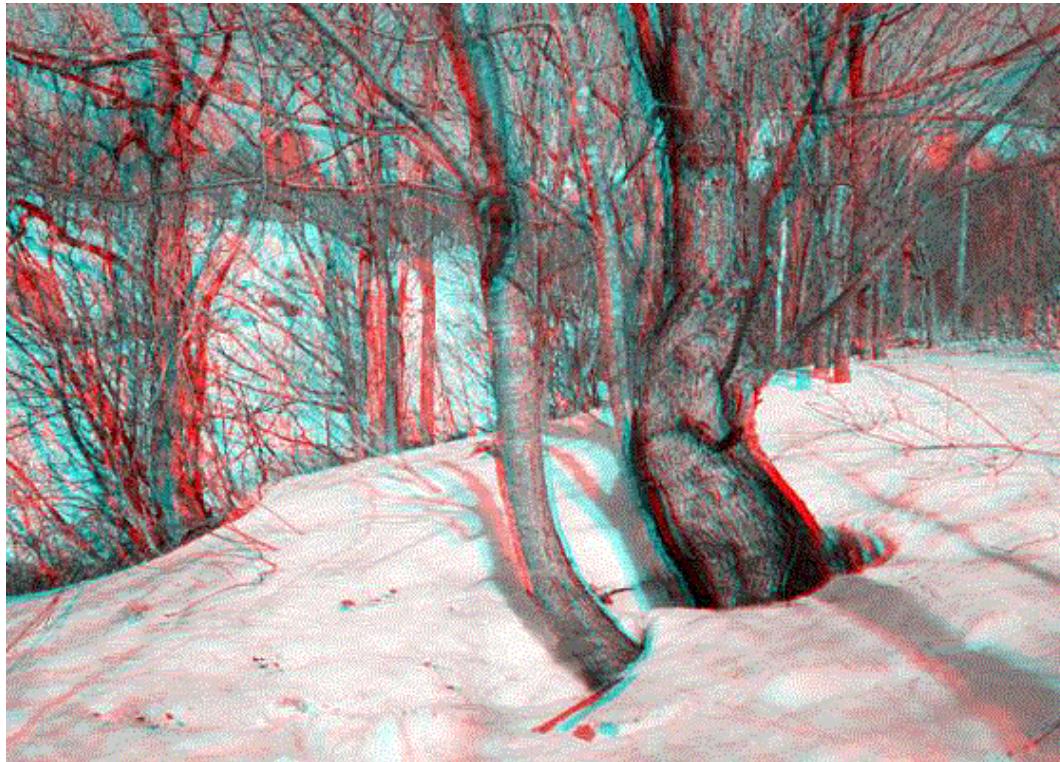

Stereograms

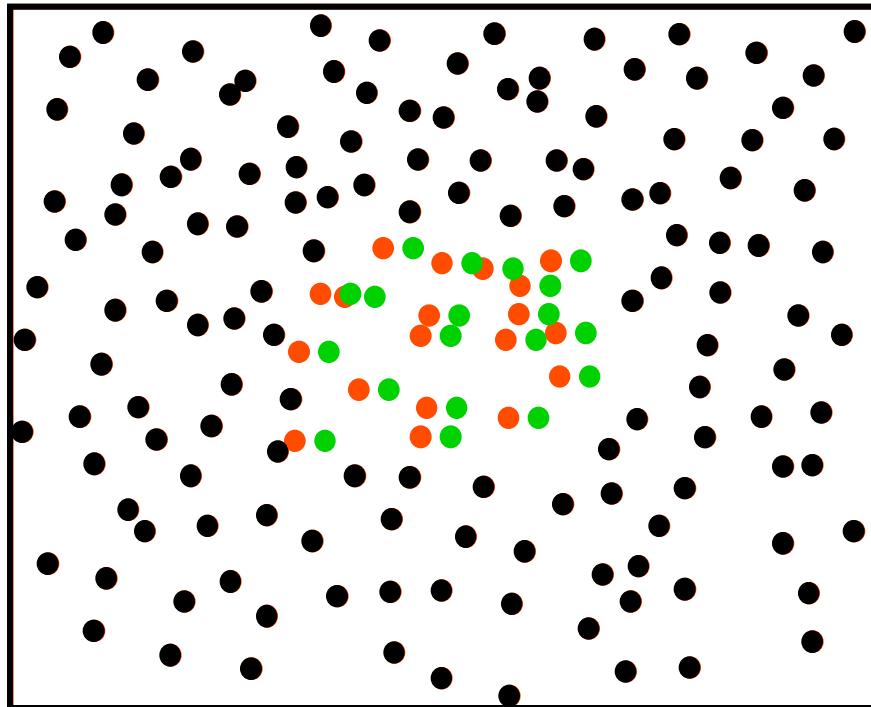

- Invented by Sir Charles Wheatstone, 1838

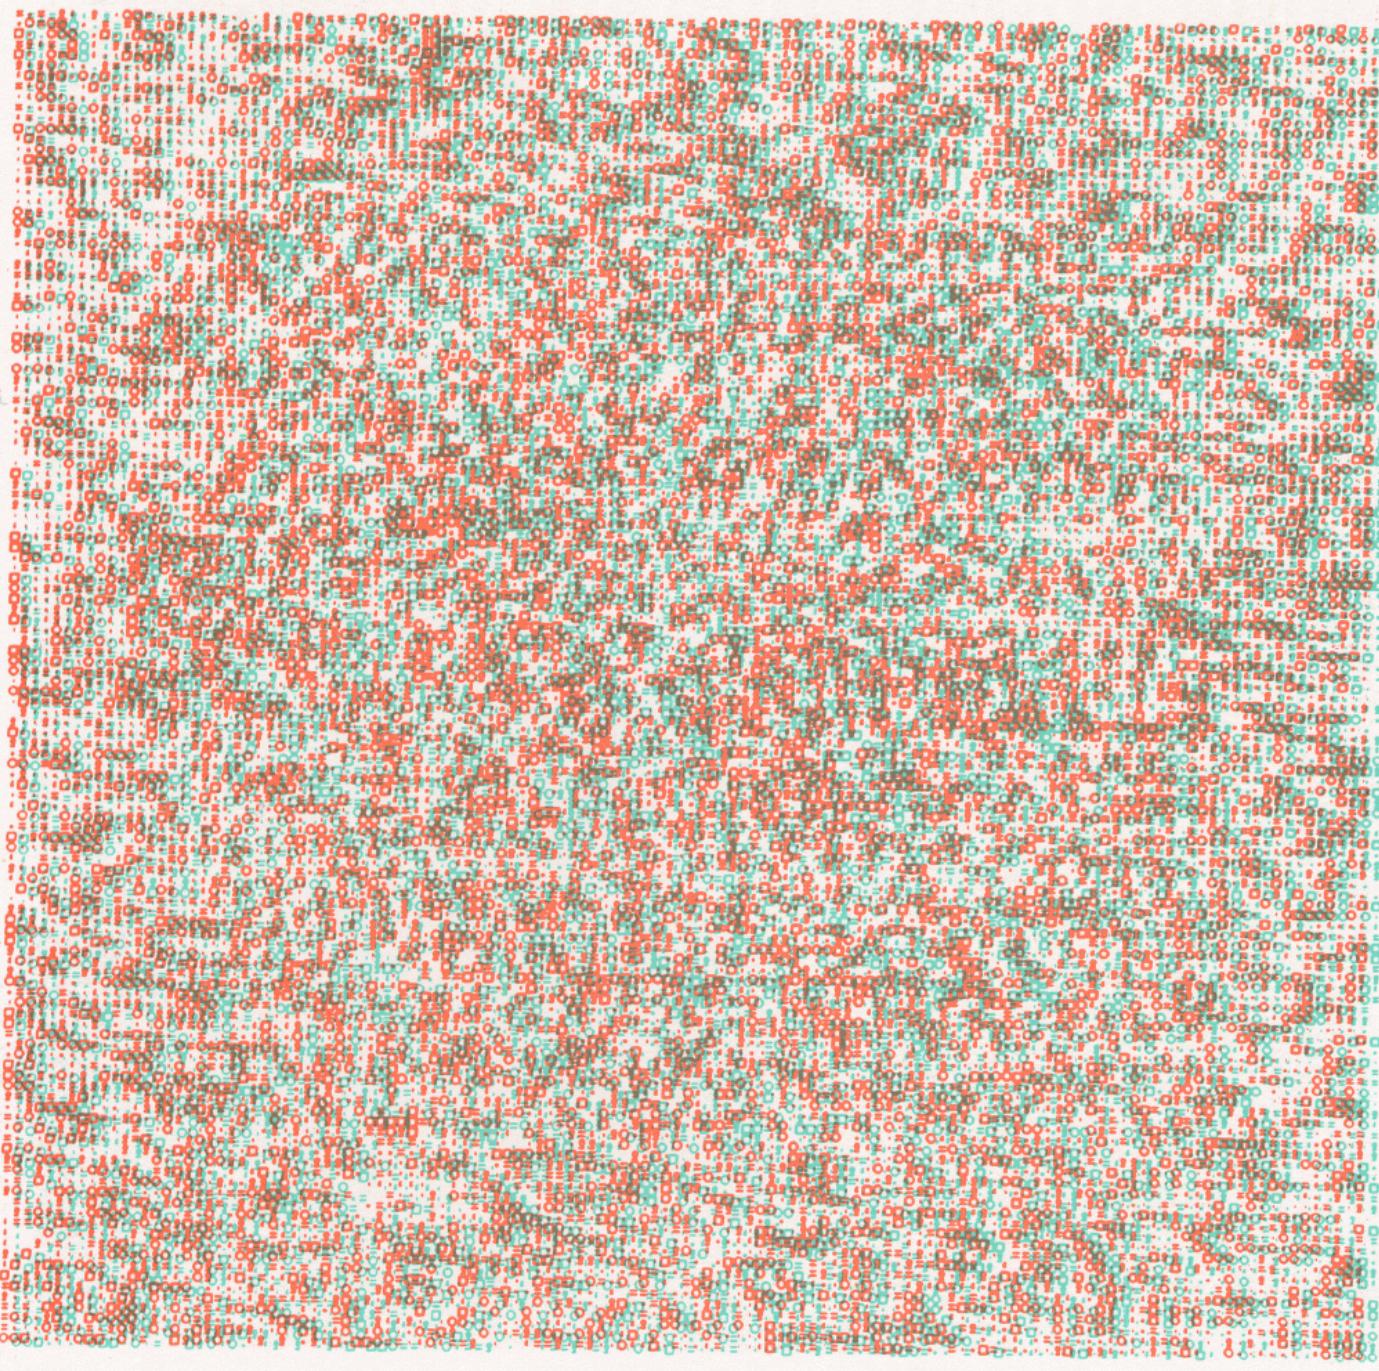

Red/green stereograms

Random dot stereograms

Autostereograms

Autostereograms: www.magiceye.com

Autostereograms

Autostereograms: www.magiceye.com

Correspondence algorithms

Algorithms may be top down or bottom up – random dot stereograms are an existence proof that bottom up algorithms are possible

From here on only consider bottom up algorithms

Algorithms may be classified into two types:

- 1. Dense: compute a correspondence at every pixel ←
- 2. Sparse: compute correspondences only for features

Example image pair – parallel cameras

First image

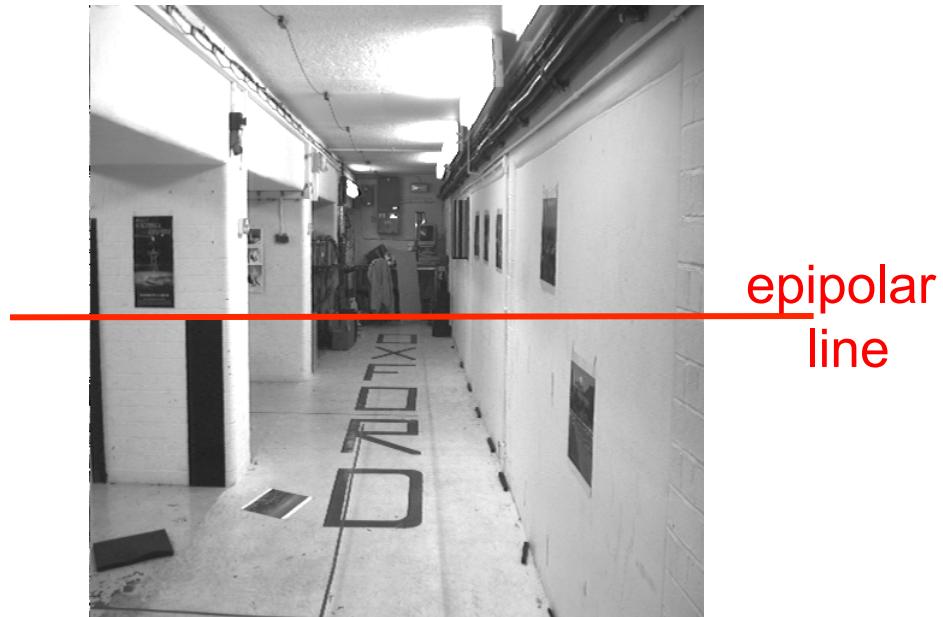

Second image

Dense correspondence algorithm

Parallel camera example – epipolar lines are corresponding rasters

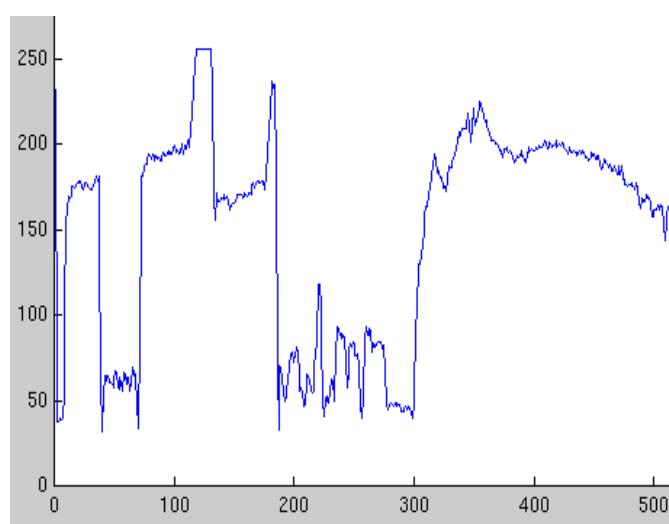

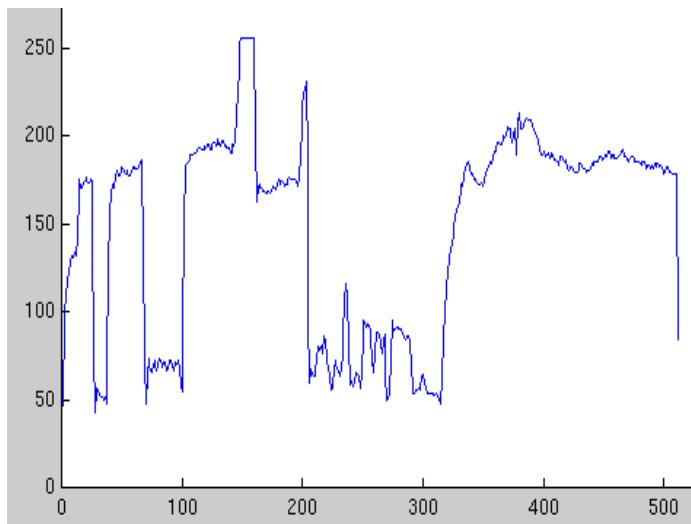

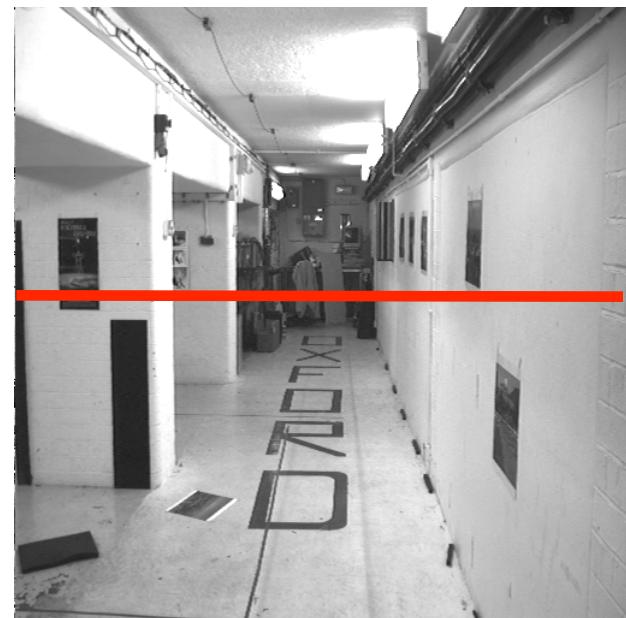

epipolar
line

Search problem (geometric constraint): for each point in the left image, the corresponding point in the right image lies on the epipolar line (1D ambiguity)

Disambiguating assumption (photometric constraint): the intensity neighbourhood of corresponding points are similar across images

Measure similarity of neighbourhood intensity by cross-correlation

Intensity profiles

- Clear correspondence between intensities, but also noise and ambiguity

Normalized Cross Correlation

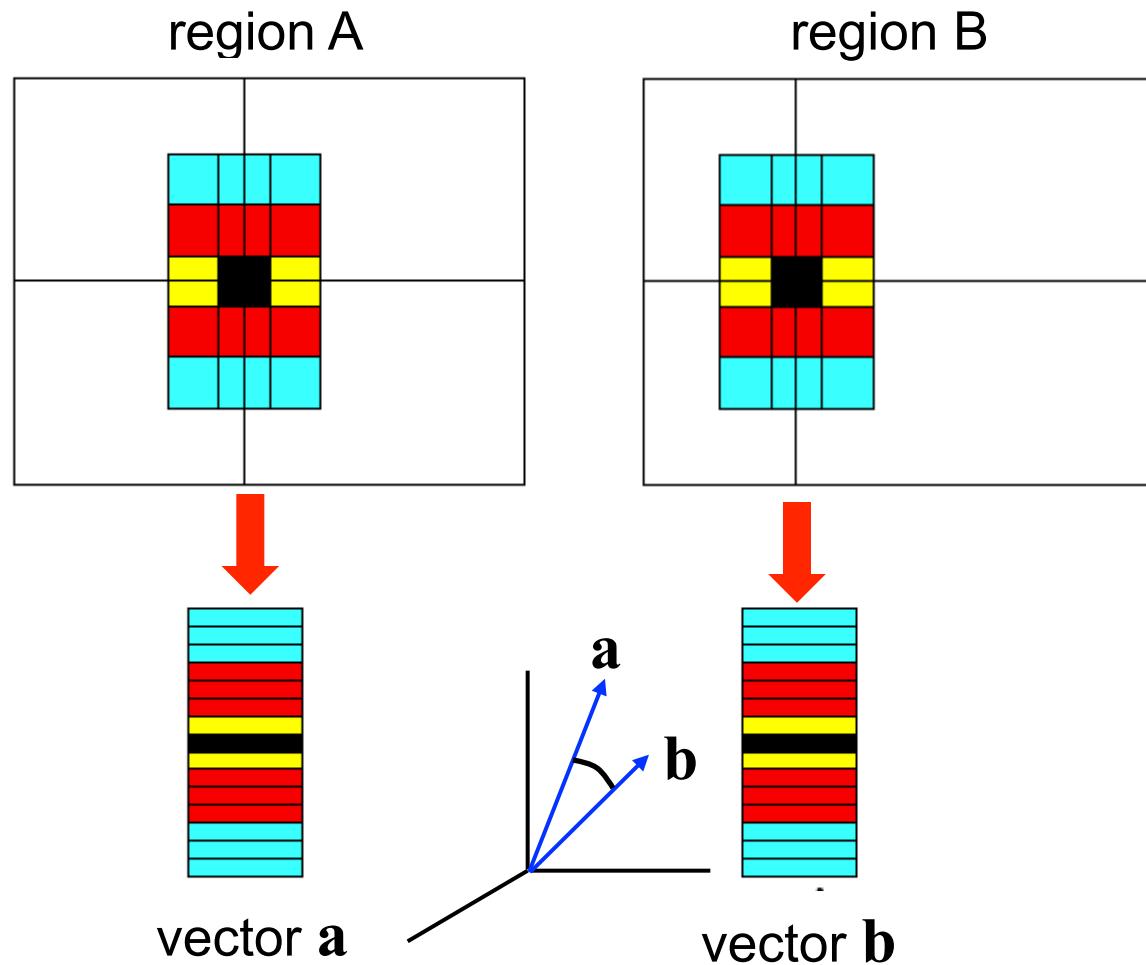

$$NCC = \frac{\sum_i \sum_j A(i, j)B(i, j)}{\sqrt{\sum_i \sum_j A(i, j)^2} \sqrt{\sum_i \sum_j B(i, j)^2}}$$

write regions as vectors

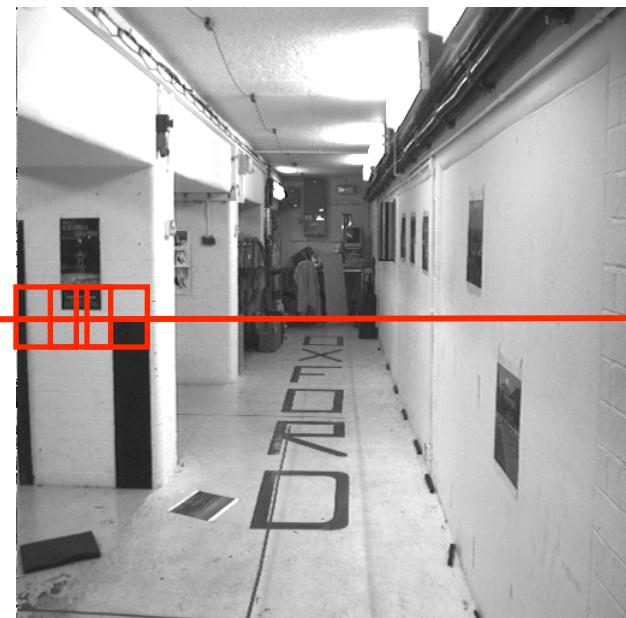

$$A \rightarrow \mathbf{a}, \quad B \rightarrow \mathbf{b}$$

$$NCC = \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}| |\mathbf{b}|}$$

$$-1 \leq NCC \leq 1$$

Cross-correlation of neighbourhood regions

regions A, B, write as vectors \mathbf{a}, \mathbf{b}

translate so that mean is zero

$$\mathbf{a} \rightarrow \mathbf{a} - \langle \mathbf{a} \rangle, \quad \mathbf{b} \rightarrow \mathbf{b} - \langle \mathbf{b} \rangle$$

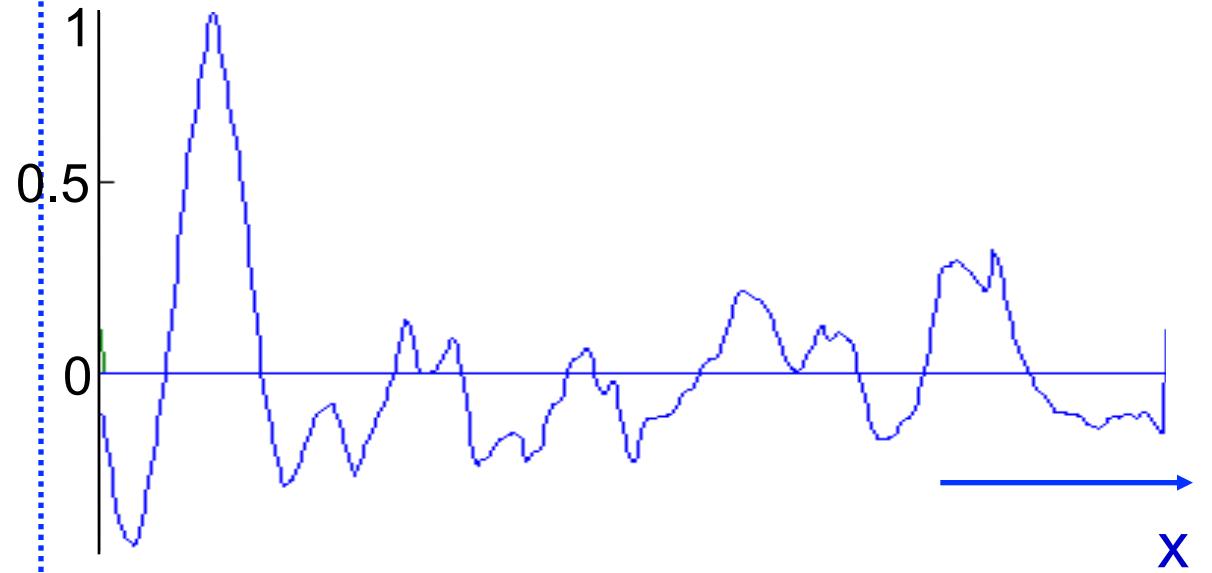

$$\text{cross correlation} = \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}| |\mathbf{b}|}$$

Invariant to $I \rightarrow \alpha I + \beta$
(exercise)

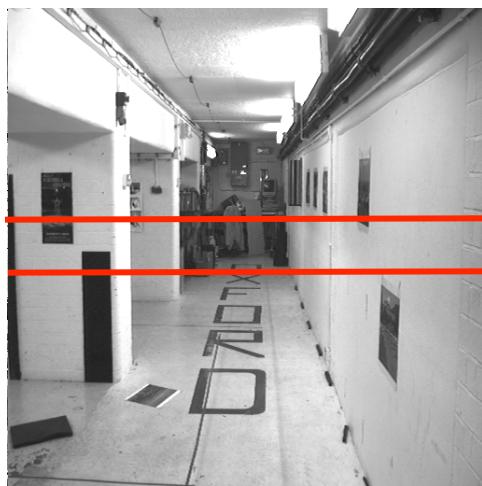

left image band

right image band

cross
correlation

x

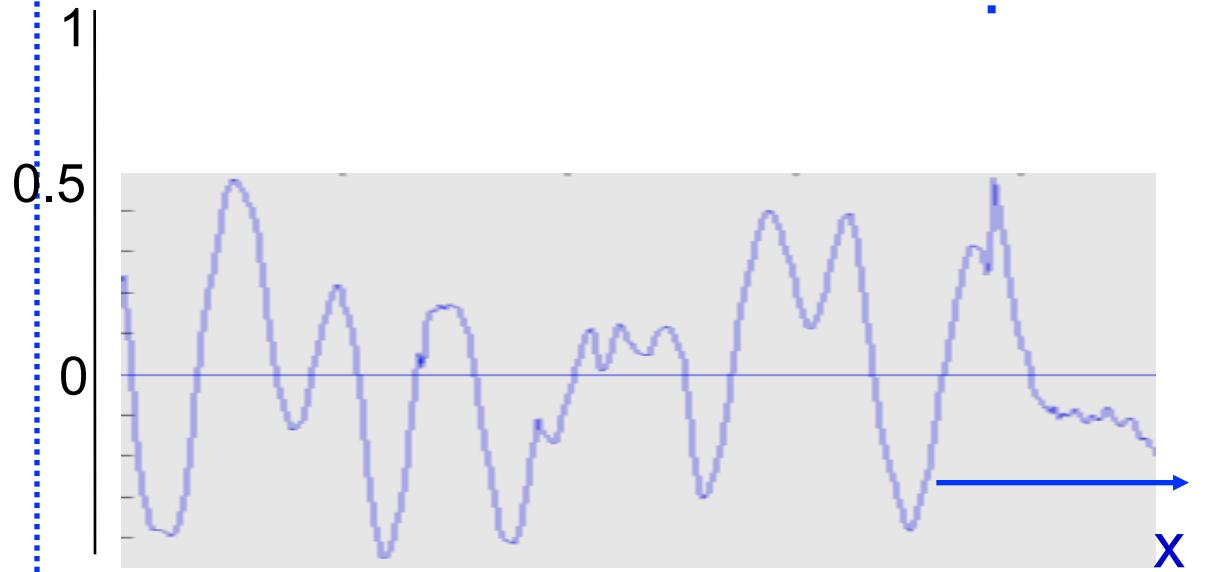

target region

left image band

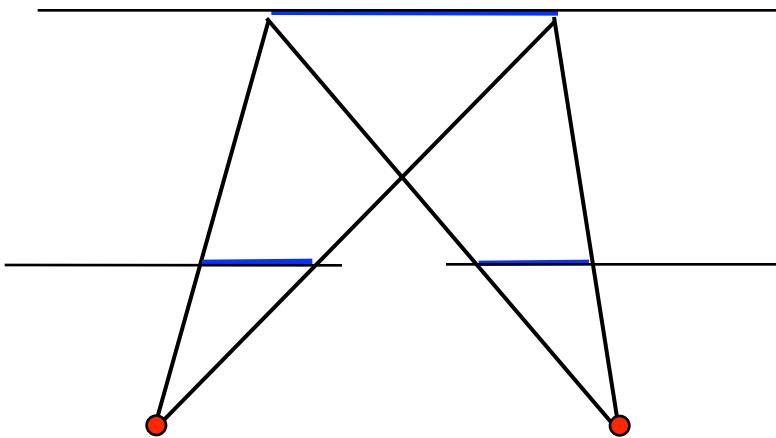

right image band

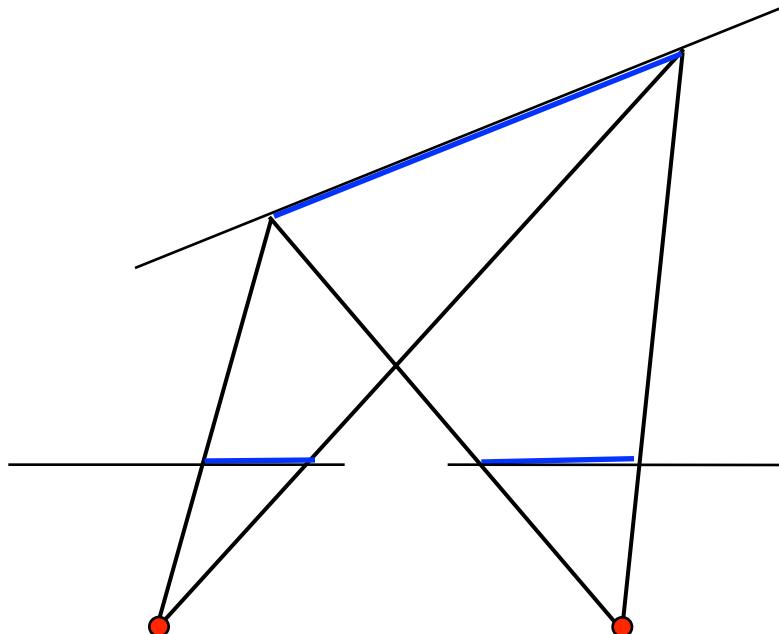

Why is cross-correlation such a poor measure in the second case?

1. The neighbourhood region does not have a “distinctive” spatial intensity distribution
2. Foreshortening effects

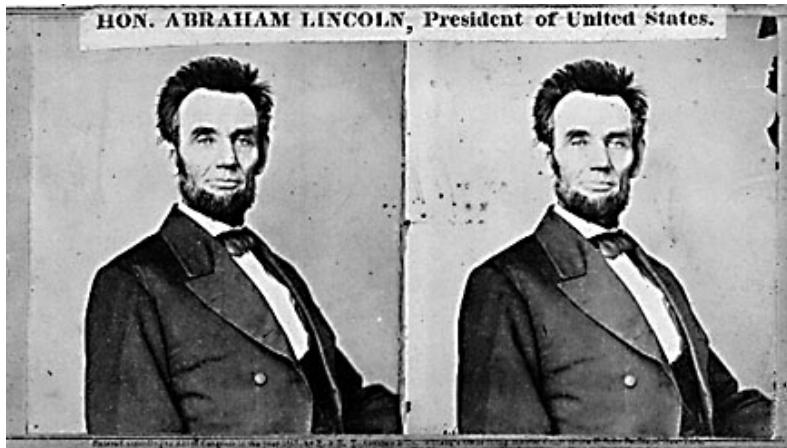

fronto-parallel surface
imaged length the same

slanting surface
imaged lengths differ

Limitations of similarity constraint

Textureless surfaces

Occlusions, repetition

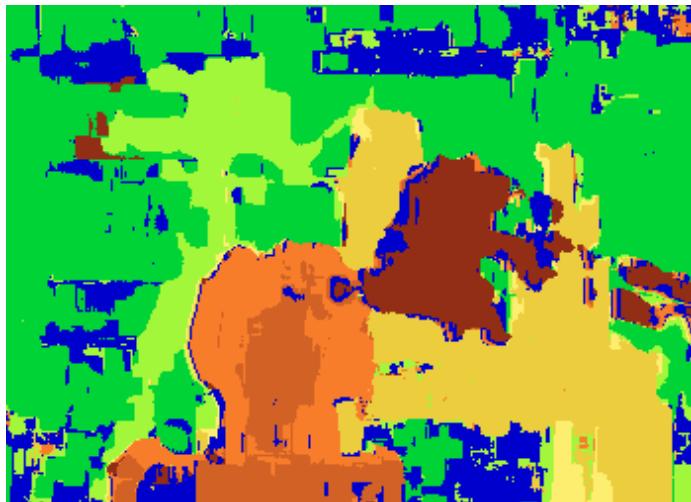

Non-Lambertian surfaces, specularities

Results with window search

Data

Window-based matching

Ground truth

Sketch of a dense correspondence algorithm

For each pixel in the left image

- compute the neighbourhood cross correlation along the corresponding epipolar line in the right image
- the corresponding pixel is the one with the highest cross correlation

Parameters

- size (scale) of neighbourhood
- search disparity

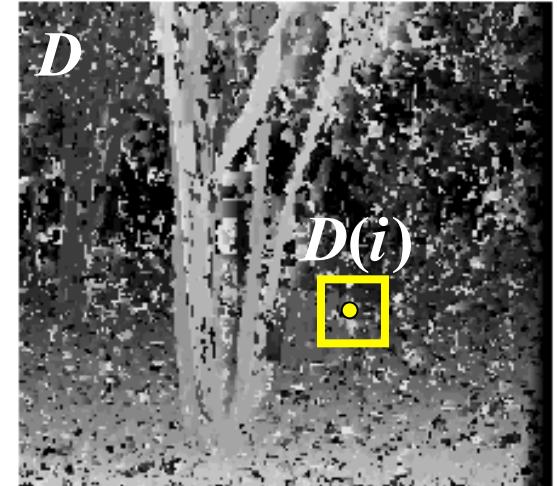

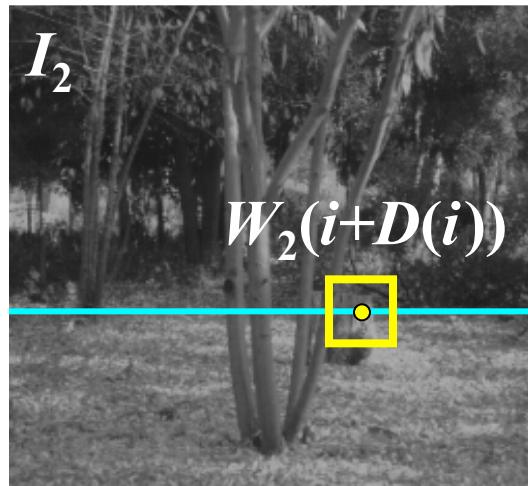

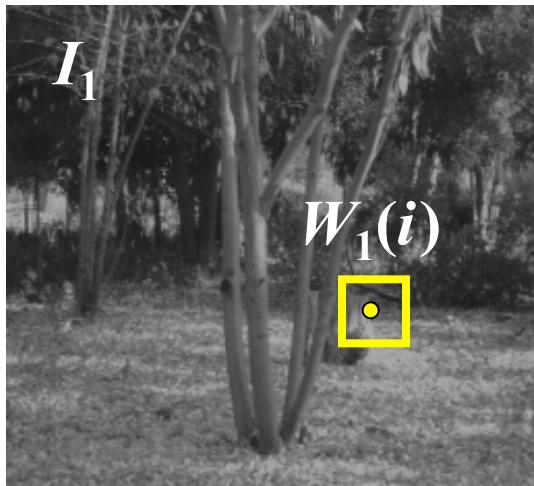

Other constraints

- uniqueness
- ordering
- smoothness of disparity field

Applicability

- textured scene, largely fronto-parallel

Stereo matching as energy minimization

MAP estimate of disparity image D : $P(D | I_1, I_2) \propto P(I_1, I_2 | D)P(D)$

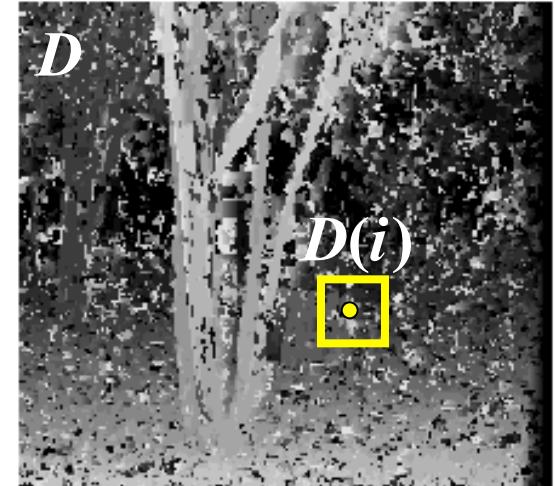

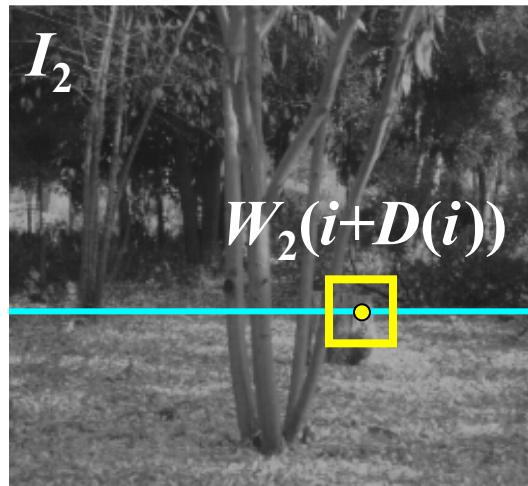

$$-\log P(D | I_1, I_2) \propto -\log P(I_1, I_2 | D) - \log P(D)$$

$$E = \alpha E_{\text{data}}(I_1, I_2, D) + \beta E_{\text{smooth}}(D)$$

$$E_{\text{data}} = \sum_i (W_1(i) - W_2(i + D(i)))^2$$

$$E_{\text{smooth}} = \sum_{\text{neighbors } i, j} \rho(D(i) - D(j))$$

Stereo matching as energy minimization

$$E = \alpha E_{\text{data}}(I_1, I_2, D) + \beta E_{\text{smooth}}(D)$$

$$E_{\text{data}} = \sum_i (W_1(i) - W_2(i + D(i)))^2$$

$$E_{\text{smooth}} = \sum_{\text{neighbors } i, j} \rho(D(i) - D(j))$$

- Energy functions of this form can be minimized using *graph cuts*

Rectification

For converging cameras

- epipolar lines are not parallel

Project images onto plane parallel to baseline

Rectification continued

Convert converging cameras to parallel camera geometry by an image mapping

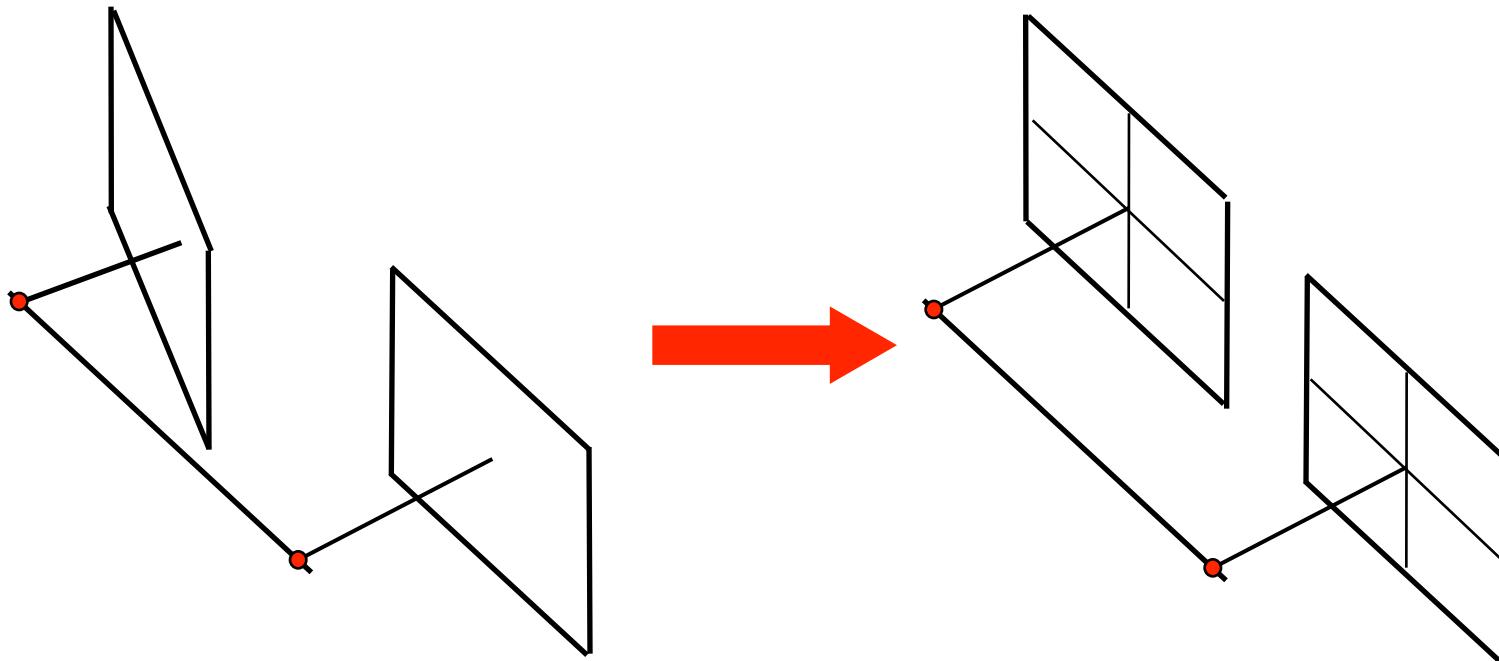

Image mapping is a 2D homography (projective transformation)

$$H = KRK^{-1} \quad (\text{exercise})$$

Rectification continued

Convert converging cameras to parallel camera geometry by an image mapping

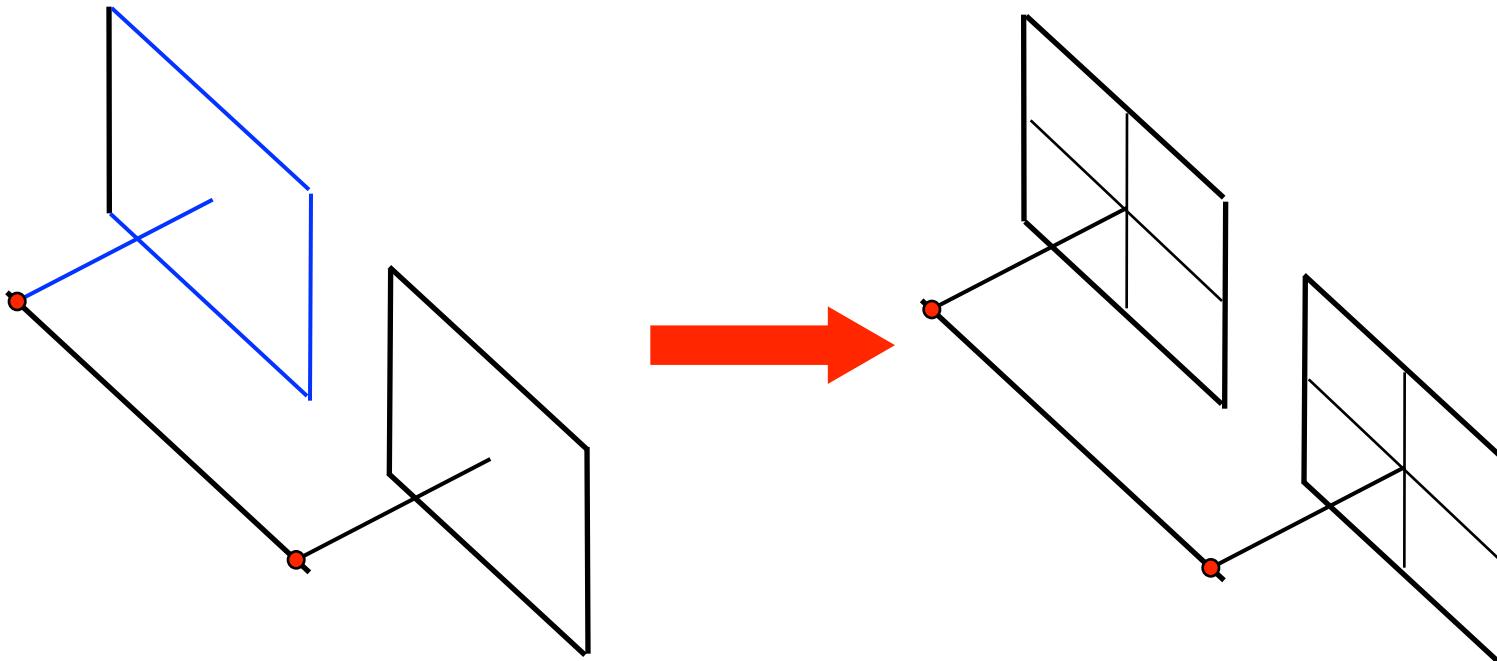

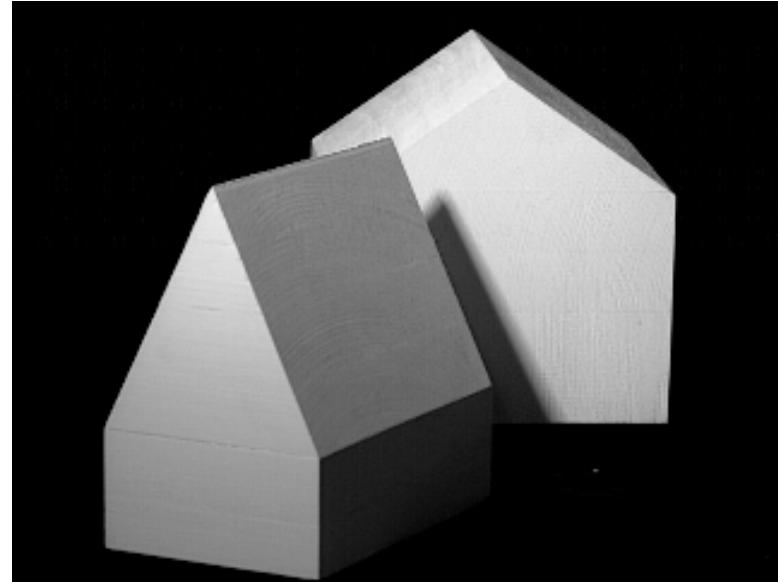

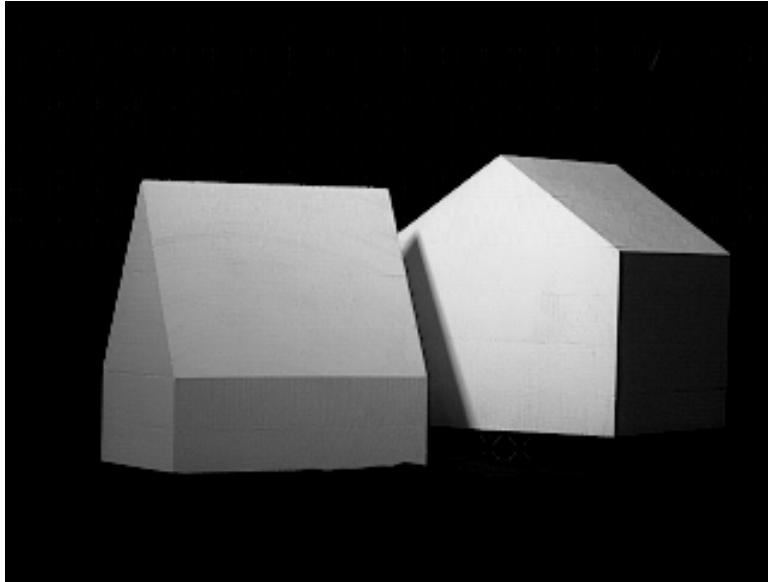

Image mapping is a 2D homography (projective transformation)

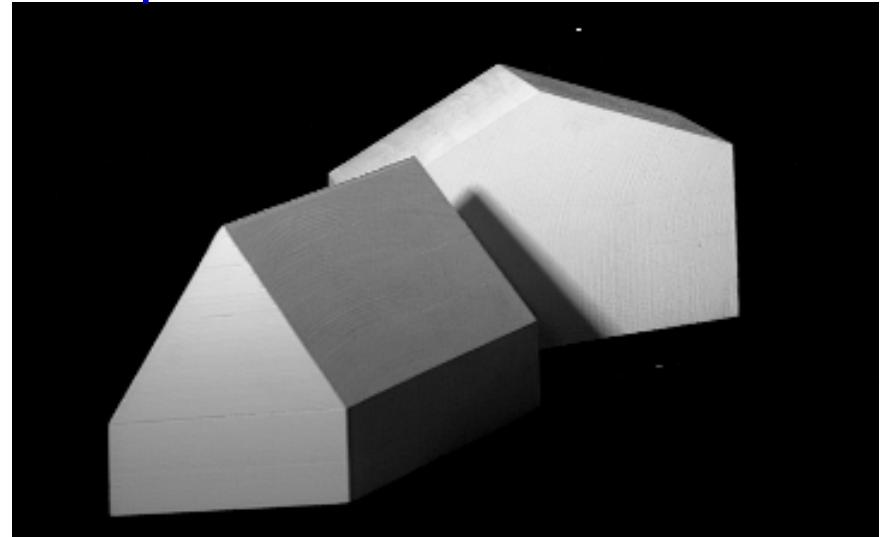

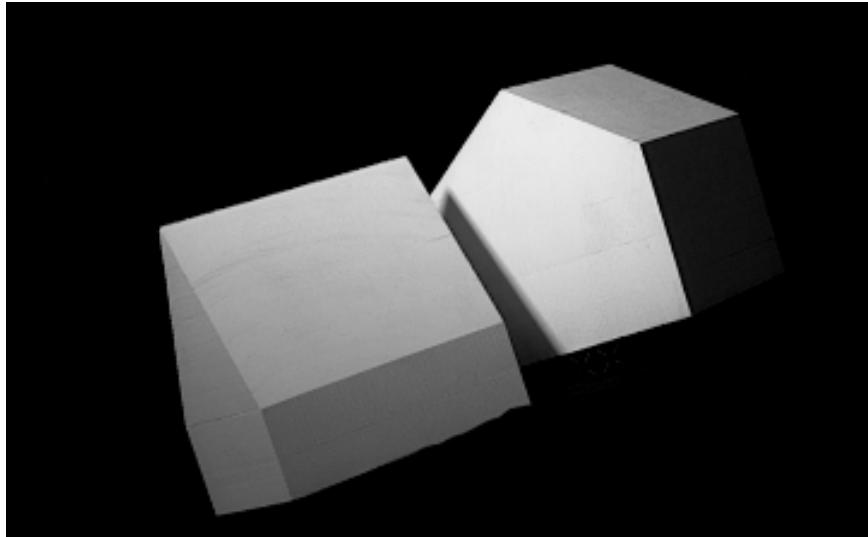

$$H = KRK^{-1} \quad (\text{exercise})$$

Example

original stereo pair

rectified stereo pair

Example: depth and disparity for a parallel camera stereo rig

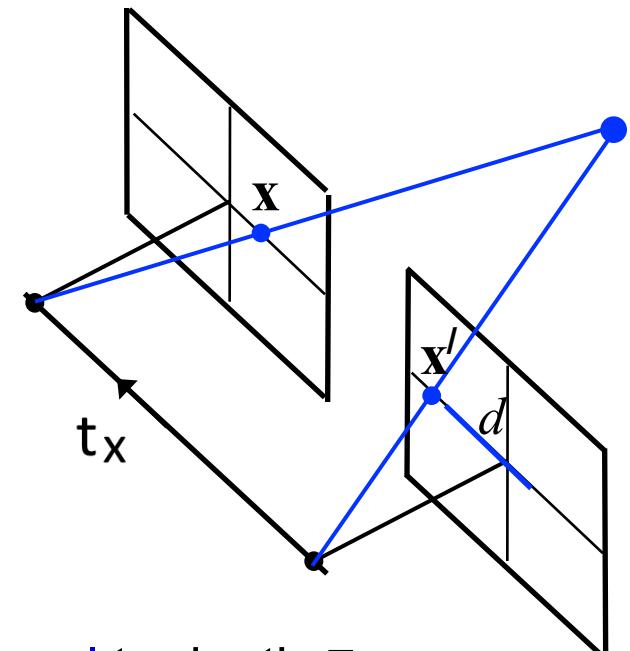

$$K = K' = \begin{bmatrix} f & 0 & 0 \\ 0 & f & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad R = I \quad t = \begin{pmatrix} t_x \\ 0 \\ 0 \end{pmatrix}$$

Then, $y' = y$, and the **disparity** $d = x' - x = \frac{ft_x}{Z}$

Derivation

$$\frac{x}{f} = \frac{X}{Z} \quad \frac{x'}{f} = \frac{X + t_x}{Z}$$

$$\frac{x'}{f} = \frac{x}{f} + \frac{t_x}{Z}$$

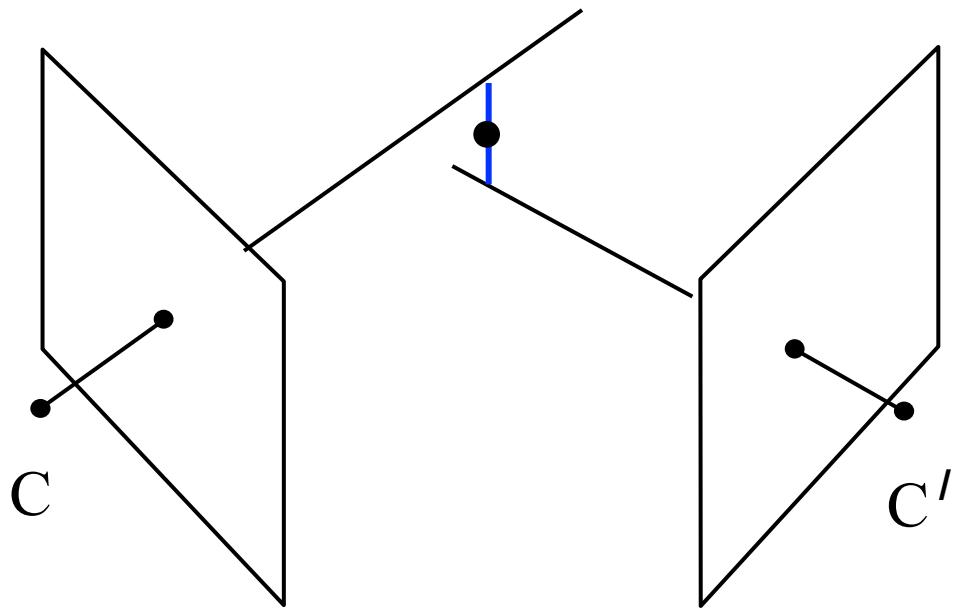

Note

- image movement (disparity) is **inversely proportional** to depth Z
as $z \rightarrow \infty$, $d \rightarrow 0$
- depth is inversely proportional to disparity

Triangulation

1. Vector solution

Compute the mid-point of the shortest line between the two rays

2. Linear triangulation (algebraic solution)

Use the equations $\mathbf{x} = \mathbf{P}\mathbf{X}$ and $\mathbf{x}' = \mathbf{P}'\mathbf{X}$ to solve for \mathbf{X}

For the first camera:

$$\mathbf{P} = \begin{bmatrix} p_{11} & p_{12} & p_{13} & p_{14} \\ p_{21} & p_{22} & p_{23} & p_{24} \\ p_{31} & p_{32} & p_{33} & p_{34} \end{bmatrix} = \begin{bmatrix} \mathbf{p}^{1\top} \\ \mathbf{p}^{2\top} \\ \mathbf{p}^{3\top} \end{bmatrix}$$

where $\mathbf{p}^{i\top}$ are the rows of \mathbf{P}

- eliminate unknown scale in $\lambda\mathbf{x} = \mathbf{P}\mathbf{X}$ by forming a cross product $\mathbf{x} \times (\mathbf{P}\mathbf{X}) = \mathbf{0}$

$$x(\mathbf{p}^{3\top}\mathbf{X}) - (\mathbf{p}^{1\top}\mathbf{X}) = 0$$

$$y(\mathbf{p}^{3\top}\mathbf{X}) - (\mathbf{p}^{2\top}\mathbf{X}) = 0$$

$$x(\mathbf{p}^{2\top}\mathbf{X}) - y(\mathbf{p}^{1\top}\mathbf{X}) = 0$$

- rearrange as (first two equations only)

$$\begin{bmatrix} x\mathbf{p}^{3\top} - \mathbf{p}^{1\top} \\ y\mathbf{p}^{3\top} - \mathbf{p}^{2\top} \end{bmatrix} \mathbf{X} = \mathbf{0}$$

Similarly for the second camera:

$$\begin{bmatrix} x' \mathbf{p}'^{\top} - \mathbf{p}^{\top} \\ y' \mathbf{p}'^{\top} - \mathbf{p}^{\top} \end{bmatrix} \mathbf{X} = \mathbf{0}$$

Collecting together gives

$$\mathbf{A}\mathbf{X} = \mathbf{0}$$

where \mathbf{A} is the 4×4 matrix

$$\mathbf{A} = \begin{bmatrix} x\mathbf{p}^{\top} - \mathbf{p}^{\top} \\ y\mathbf{p}^{\top} - \mathbf{p}^{\top} \\ x' \mathbf{p}'^{\top} - \mathbf{p}'^{\top} \\ y' \mathbf{p}'^{\top} - \mathbf{p}'^{\top} \end{bmatrix}$$

from which \mathbf{X} can be solved up to scale.

Problem: does not minimize anything meaningful

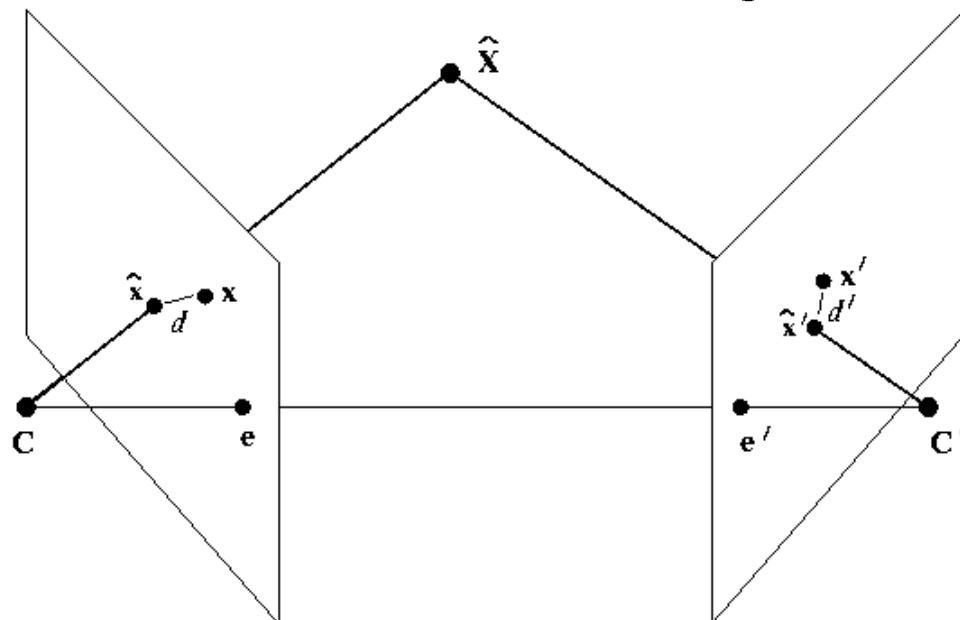

Advantage: extends to more than two views

3. Minimizing a geometric/statistical error

The idea is to estimate a 3D point \hat{x} which exactly satisfies the supplied camera geometry, so it projects as

$$\hat{x} = P\hat{X} \quad \hat{x}' = P'\hat{X}$$

and the aim is to estimate \hat{x} from the image measurements x and x' .

$$\min_{\hat{X}} \mathcal{C}(x, x') = d(x, \hat{x})^2 + d(x', \hat{x}')^2$$

where $d(*, *)$ is the Euclidean distance between the points.

- It can be shown that if the measurement noise is Gaussian mean zero, $\sim N(0, \sigma^2)$, then minimizing geometric error is the **Maximum Likelihood Estimate** of X
- The minimization appears to be over three parameters (the position X), but the problem can be reduced to a minimization over one parameter

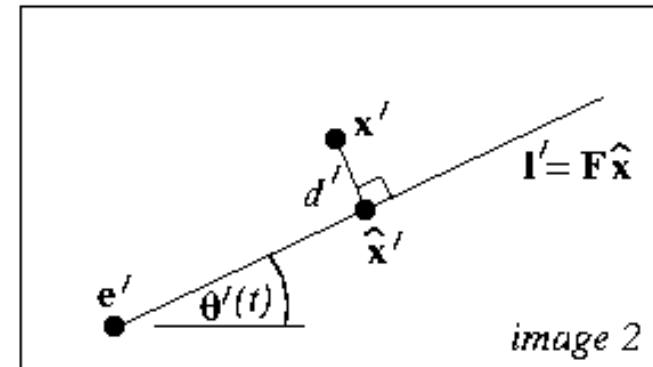

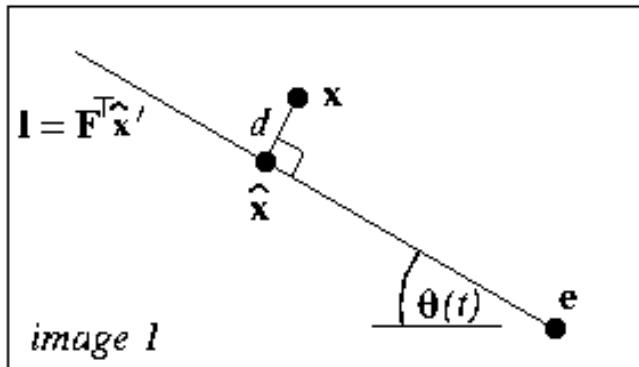

Different formulation of the problem

The minimization problem may be formulated differently:

- Minimize

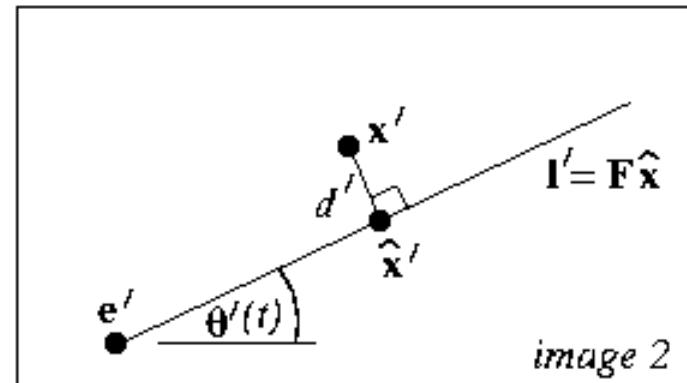

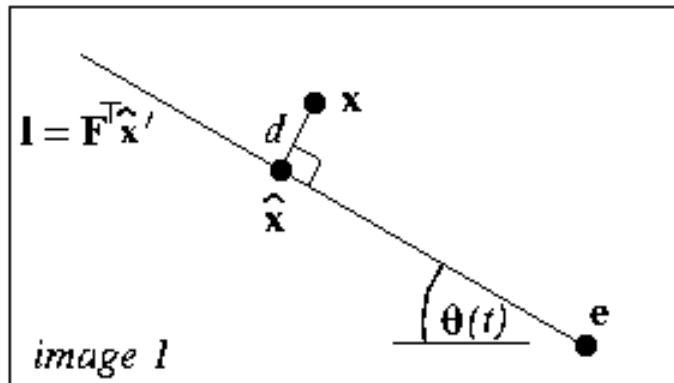

$$d(\mathbf{x}, \mathbf{l})^2 + d(\mathbf{x}', \mathbf{l}')^2$$

- \mathbf{l} and \mathbf{l}' range over all choices of corresponding epipolar lines.
- $\hat{\mathbf{x}}$ is the closest point on the line \mathbf{l} to \mathbf{x} .
- Same for $\hat{\mathbf{x}}'$.

Minimization method

- Parametrize the pencil of epipolar lines in the first image by t , such that the epipolar line is $\mathbf{l}(t)$
- Using \mathbf{F} compute the corresponding epipolar line in the second image $\mathbf{l}'(t)$
- Express the distance function $d(\mathbf{x}, \mathbf{l})^2 + d(\mathbf{x}', \mathbf{l}')^2$ explicitly as a function of t
- Find the value of t that minimizes the distance function
- Solution is a 6th degree polynomial in t

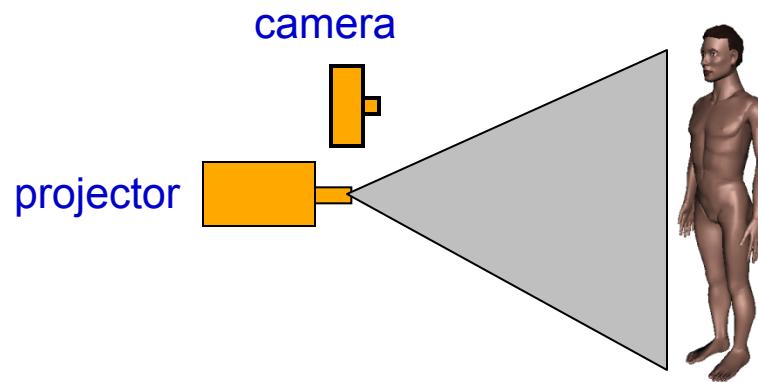

Other approaches
to obtaining 3D
structure

Active stereo with structured light

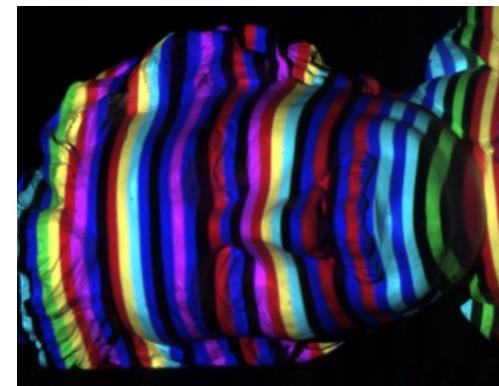

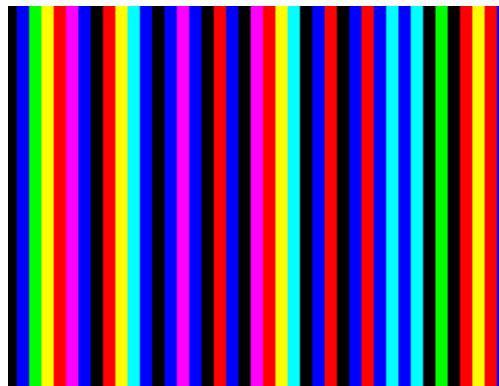

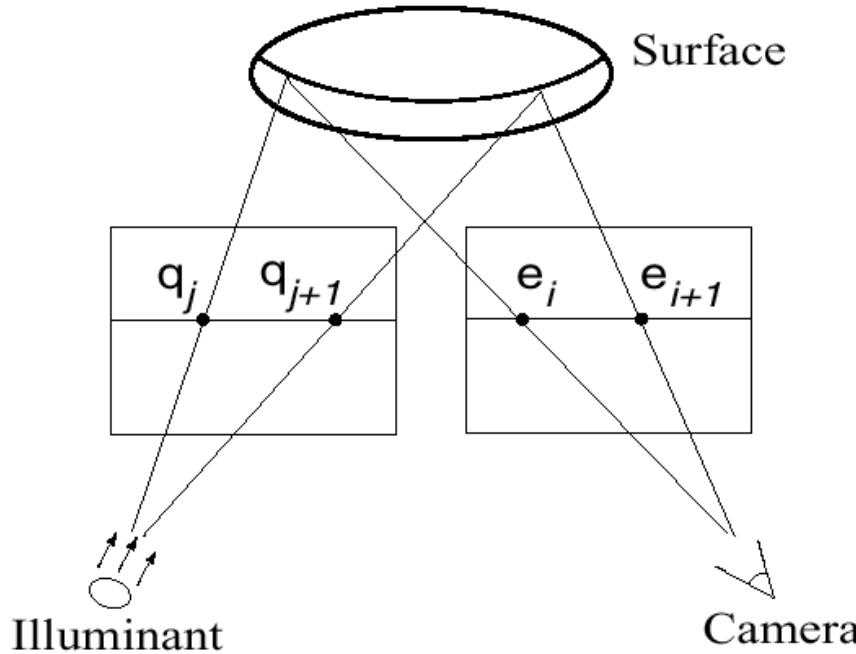

- Project “structured” light patterns onto the object
 - simplifies the correspondence problem
 - Allows us to use only one camera

Microsoft Kinect

Laser scanning

Digital Michelangelo Project
<http://graphics.stanford.edu/projects/mich/>

- Optical triangulation
 - Project a single stripe of laser light
 - Scan it across the surface of the object
 - This is a very precise version of structured light scanning

Aligning range images

- A single range scan is not sufficient to describe a complex surface
- Multiple range images can be aligned to build a model

B. Curless and M. Levoy,
A Volumetric Method for Building Complex Models from Range Images, SIGGRAPH
1996

Aligning range images

- A single range scan is not sufficient to describe a complex surface
- Need techniques to register multiple range images
 - ... which brings us to *multi-view stereo*
